(54) Title: DEVICES AND METHOD FOR ENRICHMENT AND ALTERATION OF CELLS AND OTHER PARTICLES

(57) Abstract: The invention features devices and methods for the deterministic separation of particles. Exemplary methods include the enrichment of a sample in a desired particle or the alteration of a desired particle in the device. The devices and methods are advantageously employed to enrich for rare cells, e.g., fetal cells, present in a sample, e.g., maternal blood and rare cell components, e.g., fetal cell nuclei. The invention further provides a method for preferentially lysing cells of interest in a sample, e.g., to extract clinical information from a cellular component, e.g., a nucleus, of the cells of interest. In general, the method employs differential lysis between the cells of interest and other cells (e.g., other nucleated cells) in the sample.

WO 2006/108101 A2

5                    **DEVICES AND METHODS FOR ENRICHMENT AND ALTERATION  
OF CELLS AND OTHER PARTICLES**

**BACKGROUND OF THE INVENTION**

                    The invention relates to the fields of cell separation and fluidic devices.

                    Clinically or environmentally relevant information may often be present  
10    in a sample, but in quantities too low to detect. Thus, various enrichment or  
amplification methods are often employed in order to increase the detectability  
of such information.

                    For cells, different flow cytometry and cell sorting methods are  
available, but these techniques typically employ large and expensive pieces of  
15    equipment, which require large volumes of sample and skilled operators.  
These cytometers and sorters use methods like electrostatic deflection,  
centrifugation, fluorescence activated cell sorting (FACS), and magnetic  
activated cell sorting (MACS) to achieve cell separation. These methods often  
suffer from the inability to enrich a sample sufficiently to allow analysis of rare  
20    components of the sample. Furthermore, such techniques may result in  
unacceptable losses of such rare components, e.g., through inefficient  
separation or degradation of the components.

                    Thus, there is a need for new devices and methods for enriching  
samples.

25

**SUMMARY OF THE INVENTION**

                    In general, the invention features devices that contain one or more  
structures that deterministically deflect particles, in a fluid, having a  
hydrodynamic size above a critical size in a direction not parallel to the average  
30    direction of flow of the fluid in the structure. An exemplary structure includes  
an array of obstacles that form a network of gaps, wherein a fluid passing

through the gaps is divided unequally into a major flux and a minor flux so that the average direction of the major flux is not parallel to the average direction of fluidic flow in the channel, and the major flux from the first outer region is directed either toward the second outer region or away from the second outer region, wherein the particles are directed into the major flux. The array of obstacles preferably includes first and second rows displaced laterally relative to one another so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row. Such structures may be arranged in series in a single channel, in parallel in the same channel, e.g., a duplex configuration, in parallel in multiple channels in a device, or combinations thereof. Each channel will have at least one inlet and at least one outlet. A single inlet and outlet may be employed for two or more structures in parallel, in the same or different channels. Alternatively, each structure may have its own inlet and outlet or a single structure may contain multiple inlets and outlets, e.g., to introduce or collect two different fluids simultaneously.

The invention further features methods of enriching and altering samples employing a device of the invention.

In preferred embodiments, the devices of the invention include microfluidic channels. In other preferred embodiments, the devices of the invention are configured to separate blood components, e.g., red blood cells, white blood cells, or platelets from whole blood, rare cells such as nucleated red blood cells from maternal blood, and stem cells, pathogenic or parasitic organisms, or host or graft immune cells from blood. The methods may also be employed to separate all blood cells, or portions thereof, from plasma, or all particles in a sample such as cellular components or intracellular parasites, or subsets thereof, from the suspending fluid. Other particles that may be separated in devices of the invention are described herein.

The invention further provides methods for preferentially lysing cells of interest in a sample, e.g., to extract clinical information from a cellular component, e.g., a nucleus or nucleic acid, of the cells of interest, e.g., nucleated fetal red blood cells. In general, the method employs differential

lysis between the cells of interest and other cells (e.g., other nucleated cells) in the sample. In certain embodiments, preferential lysis results in lysis of at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95%, or 99% of cells of interest, e.g., red blood cells or fetal nucleated red blood cells, and lysis of less  
5 than 50%, 40%, 30%, 20%, 10%, 5%, or 1% of undesired cells, e.g. maternal white blood cells or maternal nucleated red blood cells.

By "gap" is meant an opening through which fluids and/or particles may flow. For example, a gap may be a capillary, a space between two obstacles wherein fluids may flow, or a hydrophilic pattern on an otherwise hydrophobic  
10 surface wherein aqueous fluids are confined. In a preferred embodiment of the invention, the network of gaps is defined by an array of obstacles. In this embodiment, the gaps are the spaces between adjacent obstacles. In a preferred embodiment, the network of gaps is constructed with an array of obstacles on the surface of a substrate.

15 By "obstacle" is meant an impediment to flow in a channel, e.g., a protrusion from one surface. For example, an obstacle may refer to a post outstanding on a base substrate or a hydrophobic barrier for aqueous fluids. In some embodiments, the obstacle may be partially permeable. For example, an obstacle may be a post made of porous material, wherein the pores allow  
20 penetration of an aqueous component but are too small for the particles being separated to enter.

By "hydrodynamic size" is meant the effective size of a particle when interacting with a flow, posts, and other particles. It is used as a general term for particle volume, shape, and deformability in the flow.

25 By "flow-extracting boundary" is meant a boundary designed to remove fluid from an array.

By "flow-feeding boundary" is meant a boundary designed to add fluid to an array.

By "swelling reagent" is meant a reagent that increases the  
30 hydrodynamic radius of a particle. Swelling reagents may act by increasing the volume, reducing the deformability, or changing the shape of a particle.

By “shrinking reagent” is meant a reagent that decreases the hydrodynamic radius of a particle. Shrinking reagents may act by decreasing the volume, increasing the deformability, or changing the shape of a particle.

By “labeling reagent” is meant a reagent that is capable of binding to or  
5 otherwise being localized with a particle and being detected, e.g., through shape, morphology, color, fluorescence, luminescence, phosphorescence, absorbance, magnetic properties, or radioactive emission.

By “channel” is meant a gap through which fluid may flow. A channel may be a capillary, a conduit, or a strip of hydrophilic pattern on an otherwise  
10 hydrophobic surface wherein aqueous fluids are confined.

By “microfluidic” is meant having at least one dimension of less than 1 mm.

By “enriched sample” is meant a sample containing cells or other particles that has been processed to increase the relative population of cells or  
15 particles of interest relative to other components typically present in a sample. For example, samples may be enriched by increasing the relative population of particles of interest by at least 10%, 25%, 50%, 75%, 100% or by a factor of at least 1000, 10,000, 100,000, or 1,000,000.

By “intracellular activation” is meant activation of second messenger  
20 pathways, leading to transcription factor activation, or activation of kinases or other metabolic pathways. Intracellular activation through modulation of external cell membrane antigens can also lead to changes in receptor trafficking.

By “cellular sample” is meant a sample containing cells or components  
25 thereof. Such samples include naturally occurring fluids (e.g., blood, lymph, cerebrospinal fluid, urine, cervical lavage, and water samples) and fluids into which cells have been introduced (e.g., culture media, and liquefied tissue samples). The term also includes a lysate.

By “biological sample” is meant any same of biological origin or  
30 containing, or potentially containing, biological particles. Preferred biological samples are cellular samples.

By "biological particle" is meant any species of biological origin that is insoluble in aqueous media. Examples include cells, particulate cell components, viruses, and complexes including proteins, lipids, nucleic acids, and carbohydrates.

5 By "component" of a cell (or "cellular component") is meant any component of a cell that may be at least partially isolated upon lysis of the cell. Cellular components may be organelles (e.g., nuclei, peri-nuclear compartments, nuclear membranes, mitochondria, chloroplasts, or cell membranes), polymers or molecular complexes (e.g., lipids, polysaccharides, 10 proteins (membrane, trans-membrane, or cytosolic), nucleic acids (native, therapeutic, or pathogenic), viral particles, or ribosomes), intracellular parasites or pathogens, or other molecules (e.g., hormones, ions, cofactors, or drugs).

By "blood component" is meant any component of whole blood, including host red blood cells, white blood cells, and platelets. Blood 15 components also include the components of plasma, e.g., proteins, lipids, nucleic acids, and carbohydrates, and any other cells that may be present in blood, e.g., because of current or past pregnancy, organ transplant, or infection.

By "counterpart" is meant a cellular component, which although different at the detail level (e.g., sequence) is of the same class. Examples are 20 nuclei, mitochondria, mRNA, and ribosomes from different cell types, e.g., fetal red blood cells and maternal white blood cells.

By "preferential lysis" is meant lysing a cell of interest to a greater extent than undesired cells on the time scale of the lysis. Undesired cells typically contain the same cellular component found in the cells of interest or a 25 counterpart thereof or cellular components that damage the contents of cells of interest. Preferential lysis may result in lysis of at least 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, 90%, 95%, or 99% of cells of interest, e.g., while lysing less than 50%, 40%, 30%, 20%, 10%, 5%, or 1% of undesired cells.

Preferential lysis may also result in a ratio of lysis of cells of interest to 30 undesired cells.

Other features and advantages will be apparent from the following description and the claims.

### BRIEF DESCRIPTION OF THE DRAWINGS

5        Figures 1A-1E are schematic depictions of an array that separated cells based on deterministic lateral displacement: (A) illustrates the lateral displacement of subsequent rows; (B) illustrates how fluid flowing through a gap is divide unequally around obstacles in subsequent rows; (C) illustrates how a particle with a hydrodynamic size above the critical size is displaced  
10       laterally in the device; (D) illustrates an array of cylindrical obstacles; and (E) illustrates an array of elliptical obstacles.

Figure 2 is a schematic description illustrating the unequal division of the flux through a gap around obstacles in subsequent rows.

Figure 3 is a schematic depiction of how the critical size depends on the  
15       flow profile, which is parabolic in this example.

Figure 4 is an illustration of how shape affects the movement of particles through a device.

Figure 5 is an illustration of how deformability affects the movement of particles through a device.

20       Figure 6 is a schematic depiction of deterministic lateral displacement. Particles having a hydrodynamic size above the critical size move to the edge of the array, while particles having a hydrodynamic size below the critical size pass through the device without lateral displacement.

Figure 7 is a schematic depiction of a three-stage device.

25       Figure 8 is a schematic depiction of the maximum size and cut-off size (i.e., critical size) for the device of Figure 7.

Figure 9 is a schematic depiction of a bypass channel.

Figure 10 is a schematic depiction of a bypass channel.

Figure 11 is a schematic depiction of a three-stage device having a  
30       common bypass channel.

Figure 12 is a schematic depiction of a three-stage, duplex device having a common bypass channel.

Figure 13 is a schematic depiction of a three-stage device having a common bypass channel, where the flow through the device is substantially  
5 constant.

Figure 14 is a schematic depiction of a three-stage, duplex device having a common bypass channel, where the flow through the device is substantially constant.

Figure 15 is a schematic depiction of a three-stage device having a  
10 common bypass channel, where the fluidic resistance in the bypass channel and the adjacent stage are substantially constant.

Figure 16 is a schematic depiction of a three-stage, duplex device having a common bypass channel, where the fluidic resistance in the bypass channel and the adjacent stage are substantially constant.

15 Figure 17 is a schematic depiction of a three-stage device having two, separate bypass channels.

Figure 18 is a schematic depiction of a three-stage device having two, separate bypass channels, which are in arbitrary configuration.

Figure 19 is a schematic depiction of a three-stage, duplex device having  
20 three, separate bypass channels.

Figure 20 is a schematic depiction of a three-stage device having two, separate bypass channels, wherein the flow through each stage is substantially constant.

Figure 21 is a schematic depiction of a three-stage, duplex device having  
25 three, separate bypass channels, wherein the flow through each stage is substantially constant.

Figure 22 is a schematic depiction of a flow-extracting boundary.

Figure 23 is a schematic depiction of a flow-feeding boundary.

Figure 24 is a schematic depiction of a flow-feeding boundary, including  
30 a bypass channel.

Figure 25 is a schematic depiction of two flow-feeding boundaries flanking a central bypass channel.

Figure 26 is a schematic depiction of a device having four channels that act as on-chip flow resistors.

5        Figure 27 and 28 are schematic depictions of the effect of on-chip resistors on the relative width of two fluids flowing in a device.

Figure 29 is a schematic depiction of a duplex device having a common inlet for the two outer regions.

Figure 30A is a schematic depiction of a multiple arrays on a device.

5 nuclei.

## DETAILED DESCRIPTION OF THE INVENTION

### Device

In general, the devices include one or more arrays of obstacles that allow  
10 deterministic lateral displacement of components of fluids. Prior art devices that differ from those the present invention, but which, like those of the invention, employ obstacles for this purpose are described, e.g., in Huang et al. *Science* 304, 987-990 (2004) and U.S. Publication No. 20040144651. The devices of the invention for separating particles according to size employ an  
15 array of a network of gaps, wherein a fluid passing through a gap is divided unequally into subsequent gaps. The array includes a network of gaps arranged such that fluid passing through a gap is divided unequally, even though the gaps may be identical in dimensions.

The device uses a flow that carries cells to be separated through the  
20 array of gaps. The flow is aligned at a small angle (flow angle) with respect to a line-of-sight of the array. Cells having a hydrodynamic size larger than a critical size migrate along the line-of-sight in the array, whereas those having a hydrodynamic size smaller than the critical size follow the flow in a different direction. Flow in the device occurs under laminar flow conditions.

25 The critical size is a function of several design parameters. With reference to the obstacle array in Fig. 1, each row of posts is shifted horizontally with respect to the previous row by  $\Delta\lambda$ , where  $\lambda$  is the center-to-center distance between the posts (Fig. 1A). The parameter  $\Delta\lambda/\lambda$  (the "bifurcation ratio,"  $\epsilon$ ) determines the ratio of flow bifurcated to the left of the  
30 next post. In Fig. 1,  $\epsilon$  is 1/3, for the convenience of illustration. In general, if

the flux through a gap between two posts is  $\phi$ , the minor flux is  $\epsilon\phi$ , and the major flux is  $(1-\epsilon\phi)$  (Fig. 2). In this example, the flux through a gap is divided essentially into thirds (Fig. 1B). While each of the three fluxes through a gap weaves around the array of posts, the average direction of each flux is in the overall direction of flow. Fig. 1C illustrates the movement of a particles sized above the critical size through the array. Such particles move with the major flux, being transferred sequentially to the major flux passing through each gap.

Referring to Fig. 2, the critical size is approximately  $2R_{\text{critical}}$ , where  $R_{\text{critical}}$  is the distance between the stagnant flow line and the post. If the *center of mass* of a particle, e.g., a cell, falls at least  $R_{\text{critical}}$  away from the post, the particle would follow the major flux and move along the line-of-sight of the array. If the center of mass of a particle falls within  $R_{\text{critical}}$  of the post, it follows the minor flux in a different direction.  $R_{\text{critical}}$  can be determined if the flow profile across the gap is known (Fig. 3); it is the thickness of the layer of fluids that would make up the minor flux. For a given gap size,  $d$ ,  $R_{\text{critical}}$  can be tailored based on the bifurcation ratio,  $\epsilon$ . In general, the smaller  $\epsilon$ , the smaller  $R_{\text{critical}}$ .

In an array for deterministic lateral displacement, particles of different shapes behave as if they have different sizes (Fig. 4). For example, lymphocytes are spheres of  $\sim 5 \mu\text{m}$  diameter, and erythrocytes are biconcave disks of  $\sim 7 \mu\text{m}$  diameter, and  $\sim 1.5 \mu\text{m}$  thick. The long axis of erythrocytes (diameter) is larger than that of the lymphocytes, but the short axis (thickness) is smaller. If erythrocytes align their long axes to a flow when driven through an array of posts by the flow, their hydrodynamic size is effectively their thickness ( $\sim 1.5 \mu\text{m}$ ), which is smaller than lymphocytes. When an erythrocyte is driven through an array of posts by a hydrodynamic flow, it tends to align its long axis to the flow and behave like a  $\sim 1.5 \mu\text{m}$ -wide particle, which is effectively “smaller” than lymphocytes. The method and device may therefore separate cells according to their shapes, although the volumes of the cells could be the same. In addition, particles having different deformability behave as if

they have different sizes (Fig. 5). For example, two particles having the undeformed shape may be separated by deterministic lateral displacement, as the cell with the greater deformability may deform when it comes into contact with an obstacle in the array and change shape. Thus, separation in the device  
5 may be achieved based on any parameter that affects hydrodynamic size including the physical dimensions, the shape, and the deformability of the particle.

Referring to Figs. 6 and 7, feeding a mixture of particles, e.g., cells, of different hydrodynamic sizes from the top of the array and collecting the  
10 particles at the bottom, as shown schematically, produces two products, the output containing cells larger than the critical size,  $2R_{\text{critical}}$ , and waste containing cells smaller than the critical size. Although labeled “waste” in Fig. 7, particles below the critical size may be collected while the particles above the critical size are discarded. Both types of outputs may also be desirably  
15 collected, e.g., when fractionating a sample into two or more sub-samples. Cells larger than the gap size will get trapped inside the array. Therefore, an array has a working size range. Cells have to be larger than a critical size ( $2R_{\text{critical}}$ ) and smaller than a maximum pass-through size (array gap size) to be directed into the major flux.

20

### Uses of Devices of the Invention

The invention features improved devices for the separation of particles, including bacteria, viruses, fungi, cells, cellular components, viruses, nucleic acids, proteins, and protein complexes, according to size. The devices may be  
25 used to effect various manipulations on particles in a sample. Such manipulations include enrichment or concentration of a particle, including size based fractionization, or alteration of the particle itself or the fluid carrying the particle. Preferably, the devices are employed to enrich rare particles from a heterogeneous mixture or to alter a rare particle, e.g., by exchanging the liquid  
30 in the suspension or by contacting a particle with a reagent. Such devices

allow for a high degree of enrichment with limited stress on cells, e.g., reduced mechanical lysis or intracellular activation of cells.

Although primarily described in terms of cells, the devices of the invention may be employed with any other particles whose size allows for  
5 separation in a device of the invention.

### Array Design

*Single-stage array.* In one embodiment, a single stage contains an array of obstacles, e.g., cylindrical posts (Fig. 1D). In certain embodiments, the  
10 array has a maximum pass-through size that is several times larger than the critical size, e.g., when separating white blood cells from red blood cells. This result may be achieved using a combination of a large gap size  $d$  and a small bifurcation ratio  $\epsilon$ . In preferred embodiments, the  $\epsilon$  is at most 1/2, e.g., at most 1/3, 1/10, 1/30, 1/100, 1/300, or 1/1000. In such embodiments, the obstacle  
15 shape may affect the flow profile in the gap; however, the obstacles can be compressed in the flow direction, in order to make the array short (Fig. 1E). Single stage arrays may include bypass channels as described herein.

*Multiple-stage arrays.* In another embodiment, multiple stages are employed to separate particles over a wide range of sizes. An exemplary  
20 device is shown in Fig. 7. The device shown has three stages, but any number of stages may be employed. Typically, the cut-off size (i.e. critical size) in the first stage is larger than the cut-off in the second stage, and the first stage cut-off size is smaller than the maximum pass-through size of the second stage (Fig. 8). The same is true for the following stages. The first stage will deflect  
25 (and remove) particles, e.g., that would cause clogging in the second stage, before they reach the second stage. Similarly, the second stage will deflect (and remove) particles that would cause clogging in the third stage, before they reach the third stage. In general an array can have as many stages as desired.

As described, in a multiple-stage array, large particles, e.g., cells, that  
30 could cause clogging downstream are deflected first, and these deflected

particles need to bypass the downstream stages to avoid clogging. Thus, devices of the invention may include bypass channels that remove output from an array. Although described here in terms of removing particles above the critical size, bypass channels may also be employed to remove output from any  
5 portion of the array.

Different designs for bypass channels are as follows.

Single bypass channels. In this design, all stages share one bypass channel, or there is only one stage. The physical boundary of the bypass channel may be defined by the array boundary on one side and a sidewall on  
10 the other side (Figs. 9-11). Single bypass channels may also be employed with duplex arrays such that a central bypass channel separates the two arrays (i.e., two outer regions) (Fig. 12).

Single bypass channels may also be designed, in conjunction with an array to maintain constant flux through a device (Fig. 13). The bypass channel  
15 has varying width designed to maintain constant flux through all the stages, so that the flow in the channel does not interfere with the flow in the arrays. Such a design may also be employed with an array duplex (Fig. 14). Single bypass channels may also be designed in conjunction with the array in order to maintain substantially constant fluidic resistance through all stages (Fig 15).  
20 Such a design may also be employed with an array duplex (Fig. 16.)

Multiple bypass channels. In this design (Fig. 17), each stage has its own bypass channel, and the channels are separated from each other by sidewalls, e.g., to prevent the mixing of the contents of different channels. Large particles, e.g., cells are deflected into the major flux to the lower right  
25 corner of the first stage and then into in a bypass channel (bypass channel 1 in Fig. 17). Smaller cells that would not cause clogging in the second stage proceed to the second stage, and cells above the critical size of the second stage are deflected to the lower right corner of the second stage and into in another bypass channel (bypass channel 2 in Fig. 17). This design may be repeated for  
30 as many stages as desired. In this embodiment, the bypass channels are not fluidically connected, allowing for separate collection and other manipulations.

The bypass channels do not need to be straight or be physically parallel to each other (Fig. 18). Multiple bypass channels may also be employed with duplex arrays (Fig. 19).

Multiple bypass channels may be designed, in conjunction with an array to maintain constant flux through a device (Fig. 20). In this example, bypass channels are designed to remove an amount of flow so the flow in the array is not perturbed, i.e., substantially constant. Such a design may also be employed with an array duplex (Fig. 21). In this design, the center bypass channel may be shared between the two arrays in the duplex.

10       *Optimal Boundary Design.* If the array were infinitely large, the flow distribution would be the same at every gap. The flux  $\phi$  going through a gap would be the same, and the minor flux would be  $\varepsilon\phi$  for every gap. In practice, the boundaries of the array perturb this infinite flow pattern. Portions of the boundaries of arrays may be designed to generate the flow pattern of an infinite  
15       array. Boundaries may be flow-feeding, i.e., the boundary injects fluid into the array, or flow-extracting, i.e., the boundary extracts fluid from the array.

A preferred flow-extracting boundary widens gradually to extract  $\varepsilon\phi$  (represented by arrows in Fig. 22) from each gap at the boundary ( $d = 24 \mu\text{m}$ ,  $\varepsilon = 1/60$ ). For example, the distance between the array and the sidewall  
20       gradually increases to allow for the addition of  $\varepsilon\phi$  to the boundary from each gap along that boundary. The flow pattern inside this array is not affected by the bypass channel because of the boundary design.

A preferred flow-feeding boundary narrows gradually to feed exactly  $\varepsilon\phi$  (represented by arrows in Fig. 23) into each gap at the boundary ( $d = 24 \mu\text{m}$ ,  $\varepsilon = 1/60$ ). For example, the distance between the array and the sidewall  
25       gradually decreases to allow for the addition of  $\varepsilon\phi$  to each gap along the boundary from that boundary. Again, the flow pattern inside this array is not affected by the bypass channel because of the boundary design.

A flow-feeding boundary may also be as wide as or wider than the gaps  
30       of an array (Fig. 24) ( $d = 24 \mu\text{m}$ ,  $\varepsilon = 1/60$ ). A wide boundary may be desired if

the boundary serves as a bypass channel, e.g., to allow for collection of particles. A boundary may be employed that uses part of its entire flow to feed the array and feeds  $\varepsilon\phi$  into each gap at the boundary (represented by arrows in Fig. 24).

5 Fig. 25 shows a single bypass channel in a duplex array ( $\varepsilon = 1/10$ ,  $d = 8 \mu\text{m}$ ). The bypass channel includes two flow-feeding boundaries. The flux across the dashed line 1 in the bypass channel is  $\Phi_{\text{bypass}}$ . A flow  $\phi$  joins  $\Phi_{\text{bypass}}$  from a gap to the left of the dashed line. The shapes of the obstacles at the boundaries are adjusted so that the flows going into the arrays are  $\varepsilon\phi$  at  
 10 each gap at the boundaries. The flux at dashed line 2 is again  $\Phi_{\text{bypass}}$ .

### Device Design

#### On-chip flow resistor for defining and stabilizing flow

Devices of the invention may also employ fluidic resistors to define and stabilize flows within an array and to also define the flows collected from the  
 15 array. Fig. 26 shows a schematic of planar device; a sample, e.g., blood, inlet channel, a buffer inlet channel, a waste outlet channel, and a product outlet channel are each connected to an array. The inlets and outlets act as flow resistors. Figure 26 also shows the corresponding fluidic resistances of these different device components.

#### 20 Flow definition within the array

Figures 27 and 28 show the currents and corresponding widths of the sample and buffer flows within the array when the device has a constant depth and is operated with a given pressure drop. The flow is determined by the pressure drop divided by the resistance. In this particular device,  $I_{\text{blood}}$  and  
 25  $I_{\text{buffer}}$  are equivalent, and this determines equivalent widths of the blood and buffer streams in the array.

#### Definition of collection fraction

By controlling the relative resistance of the product and waste outlet channels, one can modulate the collection tolerance for each fraction. For

example, in this particular set of schematics, when  $R_{\text{product}}$  is greater than  $R_{\text{waste}}$ , a more concentrated product fraction will result at the expense of a potentially increased loss to and dilution of waste fraction. Conversely, when  $R_{\text{product}}$  is less than  $R_{\text{waste}}$ , a more dilute and higher yield product fraction will be collected at the expense of potential contamination from the waste stream.

#### Flow stabilization

Each of the inlet and outlet channels can be designed so that the pressure drops across the channels are appreciable to or greater than the fluctuations of the overall driving pressure. In typical cases, the inlet and outlet pressure drops are 0.001 to 0.99 times the driving pressure.

#### Multiplexed Arrays

The invention features multiplexed arrays. Putting multiple arrays on one device increases sample-processing throughput and allows for parallel processing of multiple samples or portions of the sample for different fractions or manipulations. Multiplexing is further desirable for preparative devices. The simplest multiplex device includes two devices attached in series, i.e., a cascade. For example, the output from the major flux of one device may be coupled to the input of a second device. Alternatively, the output from the minor flux of one device may be coupled to the input of the second device.

*Duplexing.* Two arrays can be disposed side-by-side, e.g., as mirror images (Fig. 29). In such an arrangement, the critical size of the two arrays may be the same or different. Moreover, the arrays may be arranged so that the major flux flows to the boundary of the two arrays, to the edge of each array, or a combination thereof. Such a duplexed array may also contain a central bypass channel disposed between the arrays, e.g., to collect particles above the critical size or to alter the sample, e.g., through buffer exchange, reaction, or labeling.

*Multiplexing on a device.* In addition to forming a duplex, two or more arrays that have separated inputs may be disposed on the same device (Fig.

30A). Such an arrangement could be employed for multiple samples, or the plurality of arrays may be connected to the same inlet for parallel processing of the same sample. In parallel processing of the same sample, the outlets may or may not be fluidically connected. For example, when the plurality of arrays  
5 has the same critical size, the outlets may be connected for high throughput sample processing. In another example, the arrays may not all have the same critical size or the particles in the arrays may not all be treated in the same manner, and the outlets may not be fluidically connected.

Multiplexing may also be achieved by placing a plurality of duplex  
10 arrays on a single device (Fig. 30B). A plurality of arrays, duplex or single, may be placed in any possible three-dimensional relationship to one another.

Devices of the invention also feature a small-footprint. Reducing the footprint of an array can lower cost, and reduce the number of collisions with obstacles to eliminate any potential mechanical damage or other effects to  
15 particles. The length of a multiple stage array can be reduced if the boundaries between stages are not perpendicular to the direction of flow. The length reduction becomes significant as the number of stages increases. Fig. 31 shows a small-footprint three-stage array.

## 20           **Additional components**

In addition to an array of gaps, devices of the invention may include additional elements, e.g., for isolating, collection, manipulation, or detection. Such elements are known in the art. Arrays may also be employed on a device having components for other types of separation, including affinity, magnetic,  
25 electrophoretic, centrifugal, and dielectrophoretic separation. Devices of the invention may also be employed with a component for two-dimensional imaging of the output from the device, e.g., an array of wells or a planar surface. Preferably, arrays of gaps as described herein are employed in conjunction with an affinity enrichment.

30           The invention may also be employed in conjunction with other enrichment devices, either on the same device or in different devices. Other

enrichment techniques are described, e.g., in International Publication Nos. 2004/029221 and 2004/113877, U.S. Patent No. 6,692,952, U.S. Application Publications 2005/0282293 and 2005/0266433, and U.S. Application No. 60/668,415, each of which is incorporated by reference.

5

### Methods of Fabrication

Devices of the invention may be fabricated using techniques well known in the art. The choice of fabrication technique will depend on the material used for the device and the size of the array. Exemplary materials for fabricating the devices of the invention include glass, silicon, steel, nickel, poly(methylmethacrylate) (PMMA), polycarbonate, polystyrene, polyethylene, polyolefins, silicones (e.g., poly(dimethylsiloxane)), and combinations thereof. Other materials are known in the art. For example, deep Reactive Ion Etching (DRIE) is used to fabricate silicon-based devices with small gaps, small obstacles and large aspect ratios (ratio of obstacle height to lateral dimension). Thermoforming (embossing, injection molding) of plastic devices can also be used, e.g., when the smallest lateral feature is 20 microns and the aspect ratio of these features is less than 3. Additional methods include photolithography (e.g., stereolithography or x-ray photolithography), molding, embossing, silicon micromachining, wet or dry chemical etching, milling, diamond cutting, Lithographie Galvanoformung and Abformung (LIGA), and electroplating. For example, for glass, traditional silicon fabrication techniques of photolithography followed by wet (KOH) or dry etching (reactive ion etching with fluorine or other reactive gas) can be employed. Techniques such as laser micromachining can be adopted for plastic materials with high photon absorption efficiency. This technique is suitable for lower throughput fabrication because of the serial nature of the process. For mass-produced plastic devices, thermoplastic injection molding, and compression molding may be suitable. Conventional thermoplastic injection molding used for mass-fabrication of compact discs (which preserves fidelity of features in sub-microns) may also be employed to fabricate the devices of the invention. For

example, the device features are replicated on a glass master by conventional photolithography. The glass master is electroformed to yield a tough, thermal shock resistant, thermally conductive, hard mold. This mold serves as the master template for injection molding or compression molding the features into a plastic device. Depending on the plastic material used to fabricate the devices and the requirements on optical quality and throughput of the finished product, compression molding or injection molding may be chosen as the method of manufacture. Compression molding (also called hot embossing or relief imprinting) has the advantages of being compatible with high-molecular weight polymers, which are excellent for small structures, but is difficult to use in replicating high aspect ratio structures and has longer cycle times. Injection molding works well for high-aspect ratio structures but is most suitable for low molecular weight polymers.

A device may be fabricated in one or more pieces that are then assembled. Layers of a device may be bonded together by clamps, adhesives, heat, anodic bonding, or reactions between surface groups (e.g., wafer bonding). Alternatively, a device with channels in more than one plane may be fabricated as a single piece, e.g., using stereolithography or other three-dimensional fabrication techniques.

To reduce non-specific adsorption of cells or compounds, e.g., released by lysed cells or found in biological samples, onto the channel walls, one or more channel walls may be chemically modified to be non-adherent or repulsive. The walls may be coated with a thin film coating (e.g., a monolayer) of commercial non-stick reagents, such as those used to form hydrogels. Additional examples chemical species that may be used to modify the channel walls include oligoethylene glycols, fluorinated polymers, organosilanes, thiols, poly-ethylene glycol, hyaluronic acid, bovine serum albumin, poly-vinyl alcohol, mucin, poly-HEMA, methacrylated PEG, and agarose. Charged polymers may also be employed to repel oppositely charged species. The type of chemical species used for repulsion and the method of attachment to the channel walls will depend on the nature of the species being repelled and the

nature of the walls and the species being attached. Such surface modification techniques are well known in the art. The walls may be functionalized before or after the device is assembled. The channel walls may also be coated in order to capture materials in the sample, e.g., membrane fragments or proteins.

5

### **Methods of Operation**

Devices of the invention may be employed in any application where the production of a sample enriched in particles above or below a critical size is desired. A preferred use of the device is in produced samples enriched in cells,  
10 e.g., rare cells. Once an enriched sample is produced, it may be collected for analysis or otherwise manipulated, e.g., through further enrichment.

The method of the invention uses a flow that carries cells to be separated through the array of gaps. The flow is aligned at a small angle (flow angle) with respect to a line-of-sight of the array. Cells having a hydrodynamic size  
15 larger than a critical size migrate along the line-of-sight in the array, whereas those having a hydrodynamic size smaller than the critical size follow the flow in a different direction. Flow in the device occurs under laminar flow conditions.

The method of the invention may be employed with concentrated  
20 samples, e.g., where particles are touching, hydrodynamically interacting with each other, or exerting an effect on the flow distribution around another particle. For example, the method can separate white blood cells from red blood cells in whole blood from a human donor. Human blood typically contains ~45% of cells by volume. Cells are in physical contact and/or coupled  
25 to each other hydrodynamically when they flow through the array. Fig. 32 shows schematically that cells are densely packed inside an array and could physically interact with each other.

### **Enrichment**

30 In one embodiment, the methods of the invention are employed to produce a sample enriched in particles of a desired hydrodynamic size.

Applications of such enrichment include concentrating particles, e.g., rare cells, and size fractionization, e.g., size filtering (selecting cells in a particular range of sizes). The methods may also be used to enrich components of cells, e.g., nuclei. Nuclei or other cellular components may be produced by manipulation  
5 of the sample, e.g., lysis as described herein, or be naturally present in the sample, e.g., via apoptosis or necrosis. Desirably, the methods of the invention retain at least 1%, 10%, 30%, 50%, 75%, 80%, 90%, 95%, 98%, or 99% of the desired particles compared to the initial mixture, while potentially enriching the desired particles by a factor of at least 1, 10, 100, 1000, 10,000, 100,000, or  
10 even 1,000,000 relative to one or more non-desired particles. The enrichment may also result in a dilution of the separated particles compared to the original sample, although the concentration of the separated particles relative to other particles in the sample has increased. Preferably, the dilution is at most 90%, e.g., at most 75%, 50%, 33%, 25%, 10%, or 1%.

15 In a preferred embodiment, the method produces a sample enriched in rare particles, e.g., cells. In general, a rare particle is a particle that is present as less than 10% of a sample. Exemplary rare particles include, depending on the sample, fetal cells, nucleated red blood cells (e.g., fetal or maternal), stem cells (e.g., undifferentiated), cancer cells, immune system cells (host or graft),  
20 epithelial cells, connective tissue cells, bacteria, fungi, viruses, parasites, and pathogens (e.g., bacterial or protozoan). Such rare particles may be isolated from samples including bodily fluids, e.g., blood, or environmental sources, e.g., pathogens in water samples. Fetal cells, e.g., nucleated RBCs, may be enriched from maternal peripheral blood, e.g., for the purpose of determining  
25 sex and identifying aneuploidies or genetic characteristics, e.g., mutations, in the developing fetus. Cancer cells may also be enriched from peripheral blood for the purpose of diagnosis and monitoring therapeutic progress. Bodily fluids or environmental samples may also be screened for pathogens or parasites, e.g., for coliform bacteria, blood borne illnesses such as sepsis, or bacterial or viral  
30 meningitis. Rare cells also include cells from one organism present in another organism, e.g., an in cells from a transplanted organ.

In addition to enrichment of rare particles, the methods of the invention may be employed for preparative applications. An exemplary preparative application includes generation of cell packs from blood. The methods of the invention may be configured to produce fractions enriched in platelets, red  
5 blood cells, and white cells. By using multiplexed devices or multistage devices, all three cellular fractions may be produced in parallel or in series from the same sample. In other embodiments, the method may be employed to separate nucleated from enucleated cells, e.g., from cord blood sources.

Using the methods of the invention is advantageous in situations where  
10 the particles being enriched are subject to damage or other degradation. As described herein, devices of the invention may be designed to enrich cells with a minimum number of collisions between the cells and obstacles. This minimization reduces mechanical damage to cells and also prevents intracellular activation of cells caused by the collisions. This gentle handling  
15 of the cells preserves the limited number of rare cells in a sample, prevents rupture of cells leading to contamination or degradation by intracellular components, and prevents maturation or activation of cells, e.g., stem cells or platelets. In preferred embodiments, cells are enriched such that fewer than 30%, 10 %, 5%, 1%, 0.1%, or even 0.01% are activated or mechanically lysed.

20 Fig. 33 shows a typical size distribution of cells in human peripheral blood. The white blood cells range from  $\sim 4 \mu\text{m}$  to  $\sim 18 \mu\text{m}$ , whereas the red blood cells are  $\sim 1.5 \mu\text{m}$  (short axis). An array designed to separate white blood cells from red blood cells typically has a cut-off size (i.e., critical size) of 2 to 4  $\mu\text{m}$  and a maximum pass-through size of greater than 18  $\mu\text{m}$ .

25 In an alternative embodiment, the device would function as a detector for abnormalities in red blood cells. The deterministic principle of sorting enables a predictive outcome of the percentage of enucleated cells deflected in the device. In a disease state, such as malarial infection or sickle cell anemia, the distortion in shape and flexibility of the red cells would significantly  
30 change the percentage of cells deflected. This change can be monitored as a first level sentry to alert to the potential of a diseased physiology to be followed

by microscopy examination of shape and size of red cells to assign the disease. The method is also generally applicable monitoring for any change in flexibility of particles in a sample.

In an alternative embodiment, the device would function as a detector for platelet aggregation. The deterministic principle of sorting enables a predictive outcome of the percentage of free platelets deflected in the device. Activated platelets would form aggregates, and the aggregates would be deflected. This change can be monitored as a first level sentry to alert the compromised efficacy of a platelet pack for reinfusion. The method is also generally applicable monitoring for any change in size, e.g., through agglomeration, of particles in a sample.

### Alteration

In other embodiments of the methods of this invention, cells of interest are contacted with an altering reagent that may chemically or physically alter the particle or the fluid in the suspension. Such applications include purification, buffer exchange, labeling (e.g., immunohistochemical, magnetic, and histochemical labeling, cell staining, and flow in-situ fluorescence hybridization (FISH)), cell fixation, cell stabilization, cell lysis, and cell activation.

Such methods allow for the transfer of particles from a sample into a different liquid. Fig. 34A shows this effect schematically for a single stage device, Fig. 34B shows this effect for a multistage device, Fig. 34C shows this effect for a duplex array, and Fig. 34D shows this effect for a multistage duplex array. By using such methods, blood cells may be separated from plasma. Such transfers of particles from one liquid to another may be also employed to effect a series of alterations, e.g., Wright staining blood on-chip. Such a series may include reacting a particle with a first reagent and then transferring the particle to a wash buffer, and then to another reagent.

Figs. 35A, 35B, 35C illustrate a further example of alteration in a two-stage device having two bypass channels. In this example, large blood particles

are moved from blood to buffer and collected in stage 1, medium blood particles are moved from blood to buffer in stage 2, and then small blood particles that are not removed from the blood in stages 1 and 2 are collected. Fig. 35B illustrates the size cut-off of the two stages, and Fig. 35C illustrates the size distribution of the three fractions collected.

Fig. 36 illustrates an example of alteration in a two-stage device having bypass channels that are disposed between the lateral edge of the array and the channel wall. Fig. 37 illustrates a device similar to that in Fig. 36, except that the two stages are connected by fluidic channels. Fig. 38 illustrates alteration in a device having two stages with a small footprint. Figs. 39A-39B illustrates alteration in a device in which the output from the first and second stages is captured in a single channel. Fig. 40 illustrates another device for use in the methods of the invention.

Fig. 41 illustrates the use of a device to perform multiple, sequential alterations on a particle. In this method, a blood particle is moved from blood into a reagent that reacts with the particle, and the reacted particle is then moved into a buffer, thereby removing the unreacted reagent or reaction byproducts. Additional steps may be added.

In another embodiment, reagents are added to the sample to selectively or nonselectively increase the hydrodynamic size of the particles within the sample. This modified sample is then pumped through an obstacle array. Because the particles are swollen and have an increased hydrodynamic diameter, it will be possible to use obstacle arrays with larger and more easily manufactured gap sizes. In a preferred embodiment, the steps of swelling and size-based enrichment are performed in an integrated fashion on a device. Suitable reagents include any hypotonic solution, e.g., deionized water, 2% sugar solution, or neat non-aqueous solvents. Other reagents include beads, e.g., magnetic or polymer, that bind selectively (e.g., through antibodies or avidin-biotin) or non-selectively.

In an alternate embodiment, reagents are added to the sample to selectively or nonselectively decrease the hydrodynamic size of the particles

within the sample. Nonuniform decrease in particles in a sample will increase the difference in hydrodynamic size between particles. For example, nucleated cells are separated from enucleated cells by hypertonically shrinking the cells. The enucleated cells can shrink to a very small particle, while the nucleated  
5 cells cannot shrink below the size of the nucleus. Exemplary shrinking reagents include hypertonic solutions.

In another embodiment, affinity functionalized beads are used to increase the volume of particles of interest relative to the other particles present in a sample, thereby allowing for the operation of an obstacle array with a larger  
10 and more easily manufactured gap size.

Enrichment and alteration may also be combined, e.g., where desired cells are contacted with a lysing reagent and cellular components, e.g., nuclei, are enriched based on size. In another example, particles may be contacted with particulate labels, e.g., magnetic beads, which bind to the particles.  
15 Unbound particulate labels may be removed based on size.

#### **Combination with other enrichment techniques**

Enrichment and alteration methods employing devices of the invention may be combined with other particulate sample manipulation techniques. In  
20 particular, further enrichment or purification of a particle may be desirable. Further enrichment may occur by any technique, including affinity enrichment. Suitable affinity enrichment techniques include contact particles of interest with affinity agents bound to channel walls or an array of obstacles.

Fluids may be driven through a device either actively or passively.  
25 Fluids may be pumped using electric field, a centrifugal field, pressure-driven fluid flow, an electro-osmotic flow, and capillary action. In preferred embodiments, the average direction of the field will be parallel to the walls of the channel that contains the array.

### Methods of Preferential Lysis

The invention further provides methods for preferentially lysing cells of interest in a sample, e.g., to extract clinical information from a cellular component, e.g., a nucleus, of the cells of interest. In general, the method  
5 employs differential lysis between the cells of interest and other cells (e.g., other nucleated cells) in the sample.

### Lysis

Cells of interest may be lysed using any suitable method. In one  
10 embodiment of the methods of this invention, cells may be lysed by being contacted with a solution that causes preferential lysis. Lysis solutions for these cells may include cell specific IgM molecules and proteins in the complement cascade to initiate complement mediated lysis. Another kind of lysis solution may include viruses that infect a specific cell type and cause lysis  
15 as a result of replication (see, e.g., Pawlik et al. Cancer 2002, 95:1171-81). Other lysis solutions include those that disrupt the osmotic balance of cells, e.g., hypotonic or hypertonic (e.g., distilled water), to cause lysis. Other lysis solutions are known in the art. Lysis may also occur by mechanical means, e.g., by passing cells through a sieve or other structure that mechanically  
20 disrupts the cells, through the addition of heat, acoustic, or light energy to lyse the cells, or through cell-regulated processes such as apoptosis and necrosis. Cells may also be lysed by subjecting them to one or more cycles of freezing and thawing. Additionally, detergents may be employed to solubilize the cell membrane, lysing the cells to liberate their contents.

25 In one embodiment, the cells of interest are rare cells, e.g., circulating cancer cells, fetal cells (such as fetal nucleated red blood cells), blood cells (such as nucleated red blood cells, including maternal and/or fetal nucleated red blood cells), immune cells, connective tissue cells, parasites, or pathogens (such as, bacteria, protozoa, and fungi). Most circulating rare cells of interest  
30 have compromised membrane integrity as a result of the immune attack from

the host RES (Reticulo-Endothelial-System), and accordingly are more susceptible to lysis.

In one embodiment, the cells of interest are lysed as they flow through a microfluidic device, e.g., as described in International Publications WO 2004/029221 and WO 2004/113877 or as described herein. In another embodiment, cells of interest are first bound to obstacles in a microfluidic device, e.g., as described in U.S. Patent No. 5,837,115, and then lysed. In this embodiment, the cellular components of cells of interest are released from the obstacles, while cellular components of undesired cells remain bound.

10

### **Collection of Cellular Components**

Desired cellular components may be separated from cell lysate by any suitable method, e.g., based on size, weight, shape, charge, hydrophilicity/hydrophobicity, chemical reactivity or inertness, or affinity. For example, nucleic acids, ions, proteins, and other charged species may be captured by ion exchange resins or separated by electrophoresis. Cellular components may also be separated based on size or weight by size exclusion chromatography, centrifugation, or filtration. Cellular components may also be separated by affinity mechanisms (i.e., a specific binding interaction, such as antibody-antigen and nucleic acid complementary interactions), e.g., affinity chromatography, binding to affinity species bound to surfaces, and affinity-based precipitation. In particular, nucleic acids, e.g., genomic DNA, may be separated by hybridization to sequence specific probes, e.g., attached to beads or an array. Cellular components may also be collected on the basis of shape or deformability or non-specific chemical interactions, e.g., chromatography or reverse phase chromatography or precipitation with salts or other reagents, e.g., organic solvents. Cellular components may also be collected based on chemical reactions, e.g., binding of free amines or thiols. Prior to collection, cellular components may also be altered to enable or enhance a particular mode of collection, e.g., via denaturation, enzymatic cleavage (such as via a protease,

30

endonuclease, exonuclease, or restriction endonuclease), or labeling or other chemical reaction.

The level of purity required for collected cellular components will depend on the particular manipulation employed and may be determined by the skilled artisan. In certain embodiments, the cellular component may not need to be isolated from the lysate, e.g., when the cellular component of interest may be analyzed or otherwise manipulated without interference from other cellular components. Affinity based manipulations (e.g., reaction with nucleic acid probes or primers, aptamers, antibodies, or sequence specific intercalating agents, with or without detectable labels) are amenable for use without purification of the cellular components.

In one embodiment, a device, e.g., as described in U.S. Application Publication 2004/0144651 or as described herein, is employed to isolate particulate cellular components of interest, e.g., nuclei, from the lysate based on size. In this embodiment, the particulate cellular components of interest may be separated from other particulate cellular components and intact cells using the device.

### **Manipulation of Cellular Components**

Once released by lysis or otherwise obtained, e.g., via size based separation methods described herein, desired cellular components may be further manipulated, e.g., identified, enumerated, reacted, isolated, or destroyed. In one embodiment, the cellular components contain nucleic acid, e.g., nuclei, mitochondria, and nuclear or cytoplasmic DNA or RNA. In particular, nucleic acids may include RNA, such as mRNA or rRNA, or DNA, such as chromosomal DNA, e.g., that has been cleaved, or DNA that has undergone apoptotic processing. Genetic analysis of the nucleic acid in the cellular component may be performed by any suitable methods, e.g., PCR, FISH, and sequencing. Genetic information may be employed to diagnose disease, status as a genetic disease carrier, or infection with pathogens or parasites. If acquired from fetal cells, genetic information relating to sex,

paternity, mutations (e.g., cystic fibrosis), and aneuploidy (e.g., trisomy 21) may be obtained. In some embodiments, analysis of fetal cells or components thereof is used to determine the presence or absence of a genetic abnormality, such as a chromosomal, DNA, or RNA abnormality. Examples of autosomal chromosome abnormalities include, but are not limited to, Angleman syndrome (15q11.2-q13), cri-du-chat syndrome (5p-), DiGeorge syndrome and Velo-cardiofacial syndrome (22q11.2), Miller-Dieker syndrome (17p13.3), Prader-Willi syndrome (15q11.2-q13), retinoblastoma (13q14), Smith-Magenis syndrome (17p11.2), trisomy 13, trisomy 16, trisomy 18, trisomy 21 (Down syndrome), triploidy, Williams syndrome (7q11.23), and Wolf-Hirschhorn (4p-). Examples of sex chromosome abnormalities include, but are not limited to, Kallman syndrome (Xp22.3), steroid sulfate deficiency (STS) (Xp22.3), X-linked ichthiosis (Xp22.3), Klinefelter syndrome (XXY); fragile X syndrome; Turner syndrome; metafemales or trisomy X; and monosomy X. Other less common chromosomal abnormalities that can be analyzed by the systems herein include, but are not limited to, deletions (small missing sections); microdeletions (a minute amount of missing material that may include only a single gene); translocations (a section of a chromosome is attached to another chromosome); and inversions (a section of chromosome is snipped out and reinserted upside down). In some embodiments, analysis of fetal cells or components thereof is used to analyze SNPs and predict a condition of the fetus based on such SNPs. If acquired from cancer cells, genetic information relating to tumorigenic properties may be obtained. If acquired from viral or bacterial cells, genetic information relating to the pathogenicity and classification may be obtained. For non-genetic cellular components, the components may be analyzed to diagnose disease or to monitor health. For example, proteins or metabolites from rare cells, e.g., fetal cells, may be analyzed by any suitable method, including affinity-based assays (e.g., ELISA) or other analytical techniques, e.g., chromatography and mass spectrometry.

### General Considerations

Samples may be employed in the methods described herein with or without purification, e.g., stabilization and removal of certain components.

- 5 Some sample may be diluted or concentrated prior to introduction into the device.

In another embodiment of the methods of this invention, a sample is contacted with a microfluidic device containing a plurality of obstacles, e.g., as described in U.S. Patent No. 5,837,115 or as described herein. Cells of interest  
10 bind to affinity moieties bound to the obstacles in such a device and are thereby enriched relative to undesired cells, e.g., as described in WO 2004/029221.

In another embodiment of the methods of the invention employing a similar device, cells of non-interest bind to affinity moieties bound to the obstacles, while allowing the cells of interest to pass through resulting in an  
15 enriched sample with cells of interest, e.g., as described in WO 2004/029221. The sized based method and the affinity-based method may also be combined in a two-step method to further enrich a sample in cells of interest.

In another embodiment of the methods of the invention, a cell sample is pre-filtered by contact with a microfluidic device containing a plurality of  
20 obstacles disposed such that particles above a certain size are deflected to travel in a direction not parallel to the average direction of fluid flow, e.g., as described in U.S. Application Publication 2004/0144651 or as described herein.

### EXAMPLES

- 25 **Example 1. A silicon device multiplexing 14 3-stage array duplexes**  
Figures 42A-42E show an exemplary device of the invention, characterized as follows.

Dimension: 90 mm × 34mm × 1mm

- Array design: 3 stages, gap size = 18, 12, and 8 μm for the first, second  
30 and third stage, respectively. Bifurcation ratio = 1/10. Duplex; single bypass channel

Device design: multiplexing 14 array duplexes; flow resistors for flow stability

Device fabrication: The arrays and channels were fabricated in silicon using standard photolithography and deep silicon reactive etching techniques.

- 5 The etch depth is 150  $\mu\text{m}$ . Through holes for fluid access are made using KOH wet etching. The silicon substrate was sealed on the etched face to form enclosed fluidic channels using a blood compatible pressure sensitive adhesive (9795, 3M, St Paul, MN).

- Device Packaging: The device was mechanically mated to a plastic  
10 manifold with external fluidic reservoirs to deliver blood and buffer to the device and extract the generated fractions.

Device Operation: An external pressure source was used to apply a pressure of 2.4 PSI to the buffer and blood reservoirs to modulate fluidic delivery and extraction from the packaged device.

- 15 **Experimental conditions:** human blood from consenting adult donors was collected into K<sub>2</sub>EDTA vacutainers (366643, Becton Dickinson, Franklin Lakes, NJ). The undiluted blood was processed using the exemplary device described above (Fig. 42F) at room temperature and within 9 hrs of draw. Nucleated cells from the blood were separated from enucleated cells (red blood  
20 cells and platelets), and plasma delivered into a buffer stream of calcium and magnesium-free Dulbecco's Phosphate Buffered Saline (14190-144, Invitrogen, Carlsbad, CA) containing 1% Bovine Serum Albumin (BSA) (A8412-100ML, Sigma-Aldrich, St Louis, MO).

- Measurement techniques:** Complete blood counts were determined  
25 using a Coulter impedance hematology analyzer (COULTER® Ac-T diff™, Beckman Coulter, Fullerton, CA).

- Performance:** Figs. 43A-43F shows typical histograms generated by the hematology analyzer from a blood sample and the waste (buffer, plasma, red blood cells, and platelets) and product (buffer and nucleated cells) fractions  
30 generated by the device. The following table shows the performance over 5 different blood samples:

Sample number	Throughput	Performance Metrics		
		RBC removal	Platelet removal	WBC loss
1	4 mL/hr	100%	99%	<1%
2	6 mL/hr	100%	99%	<1%
3	6 mL/hr	100%	99%	<1%
4	6 mL/hr	100%	97%	<1%
5	6 mL/hr	100%	98%	<1%

**Example 2. A silicon device multiplexing 14 single-stage array duplexes**

Figures 44 shows an exemplary device of the invention, characterized as follows.

Dimension: 90 mm × 34mm × 1mm

Array design: 1 stage, gap size = 24 μm. Bifurcation ratio = 1/60.

Duplex; double bypass channel

Device design: multiplexing 14 array duplexes; flow resistors for flow stability

Device fabrication: The arrays and channels were fabricated in silicon using standard photolithography and deep silicon reactive etching techniques. The etch depth is 150 μm. Through holes for fluid access are made using KOH wet etching. The silicon substrate was sealed on the etched face to form enclosed fluidic channels using a blood compatible pressure sensitive adhesive (9795, 3M, St Paul, MN).

Device Packaging: The device was mechanically mated to a plastic manifold with external fluidic reservoirs to deliver blood and buffer to the device and extract the generated fractions.

Device Operation: An external pressure source was used to apply a pressure of 2.4 PSI to the buffer and blood reservoirs to modulate fluidic delivery and extraction from the packaged device.

**Experimental conditions:** human blood from consenting adult donors was collected into K<sub>2</sub>EDTA vacutainers (366643, Becton Dickinson, Franklin Lakes, NJ). The undiluted blood was processed using the exemplary device described above at room temperature and within 9 hrs of draw. Nucleated cells  
5 from the blood were separated from enucleated cells (red blood cells and platelets), and plasma delivered into a buffer stream of calcium and magnesium-free Dulbecco's Phosphate Buffered Saline (14190-144, Invitrogen, Carlsbad, CA) containing 1% Bovine Serum Albumin (BSA) (A8412-100ML, Sigma-Aldrich, St Louis, MO).

10       **Measurement techniques:** Complete blood counts were determined using a Coulter impedance hematology analyzer (COULTER® Ac-T diff™, Beckman Coulter, Fullerton, CA).

**Performance:** The device operated at 17 mL/hr and achieved >99% red blood cell removal, >95% nucleated cell retention, and >98% platelet removal.

15

### **Example 3. Separation of Fetal Cord Blood**

Figure 45 shows a schematic of the device used to separate nucleated cells from fetal cord blood.

20       **Dimension:** 100 mm × 28 mm × 1mm

**Array design:** 3 stages, gap size = 18, 12, and 8 μm for the first, second and third stage, respectively. Bifurcation ratio = 1/10. Duplex; single bypass channel.

25       **Device design:** multiplexing 10 array duplexes; flow resistors for flow stability

**Device fabrication:** The arrays and channels were fabricated in silicon using standard photolithography and deep silicon reactive etching techniques. The etch depth is 140 μm. Through holes for fluid access are made using KOH wet etching. The silicon substrate was sealed on the etched face to form  
30 enclosed fluidic channels using a blood compatible pressure sensitive adhesive (9795, 3M, St Paul, MN).

Device Packaging: The device was mechanically mated to a plastic manifold with external fluidic reservoirs to deliver blood and buffer to the device and extract the generated fractions.

Device Operation: An external pressure source was used to apply a pressure of 2.0 PSI to the buffer and blood reservoirs to modulate fluidic delivery and extraction from the packaged device.

**Experimental conditions:** Human fetal cord blood was drawn into phosphate buffered saline containing Acid Citrate Dextrose anticoagulants. One milliliter of blood was processed at 3 mL/hr using the device described above at room temperature and within 48 hrs of draw. Nucleated cells from the blood were separated from enucleated cells (red blood cells and platelets), and plasma delivered into a buffer stream of calcium and magnesium-free Dulbecco's Phosphate Buffered Saline (14190-144, Invitrogen, Carlsbad, CA) containing 1% Bovine Serum Albumin (BSA) (A8412-100ML, Sigma-Aldrich, St Louis, MO) and 2 mM EDTA (15575-020, Invitrogen, Carlsbad, CA).

**Measurement techniques:** Cell smears of the product and waste fractions (Figure 46A-46B) were prepared and stained with modified Wright-Giemsa (WG16, Sigma Aldrich, St. Louis, MO).

**Performance:** Fetal nucleated red blood cells were observed in the product fraction (Figure 46A) and absent from the waste fraction (Figure 46B).

#### **Example 4. Isolation of Fetal Cells from Maternal blood**

The device and process described in detail in Example 1 were used in combination with immunomagnetic affinity enrichment techniques to demonstrate the feasibility of isolating fetal cells from maternal blood.

**Experimental conditions:** blood from consenting maternal donors carrying male fetuses was collected into K<sub>2</sub>EDTA vacutainers (366643, Becton Dickinson, Franklin Lakes, NJ) immediately following elective termination of pregnancy. The undiluted blood was processed using the device described in Example 1 at room temperature and within 9 hrs of draw. Nucleated cells from the blood were separated from enucleated cells (red blood cells and platelets),

and plasma delivered into a buffer stream of calcium and magnesium-free Dulbecco's Phosphate Buffered Saline (14190-144, Invitrogen, Carlsbad, CA) containing 1% Bovine Serum Albumin (BSA) (A8412-100ML, Sigma-Aldrich, St Louis, MO). Subsequently, the nucleated cell fraction was labeled with anti-  
5 CD71 microbeads (130-046-201, Miltenyi Biotech Inc., Auburn, CA) and enriched using the MiniMACS™ MS column (130-042-201, Miltenyi Biotech Inc., Auburn, CA) according to the manufacturer's specifications. Finally, the CD71-positive fraction was spotted onto glass slides.

**Measurement techniques:** Spotted slides were stained using  
10 fluorescence *in situ* hybridization (FISH) techniques according to the manufacturer's specifications using Vysis probes (Abbott Laboratories, Downer's Grove, IL). Samples were stained from the presence of X and Y chromosomes. In one case, a sample prepared from a known Trisomy 21 pregnancy was also stained for chromosome 21.

15 **Performance:** Isolation of fetal cells was confirmed by the reliable presence of male cells in the CD71-positive population prepared from the nucleated cell fractions (Figure 47). In the single abnormal case tested, the trisomy 21 pathology was also identified (Figure 48).

20 The following examples show specific embodiments of devices of the invention. The description for each device provides the number of stages in series, the gap size for each stage,  $\epsilon$  (Flow Angle), and the number of channels per device (Arrays/Chip). Each device was fabricated out of silicon using  
25 DRIE, and each device had a thermal oxide layer.

#### **Example 5.**

This device includes five stages in a single array.

*Array Design:* 5 stage, asymmetric array

*Gap Sizes:* Stage 1: 8  $\mu\text{m}$   
Stage 2: 10  $\mu\text{m}$   
Stage 3: 12  $\mu\text{m}$   
Stage 4: 14  $\mu\text{m}$   
Stage 5: 16  $\mu\text{m}$

*Flow Angle:* 1/10

*Arrays/Chip:* 1

**Example 6.**

This device includes three stages, where each stage is a duplex having a  
5 bypass channel. The height of the device was 125  $\mu\text{m}$ .

*Array Design:* symmetric 3 stage array with central collection channel

*Gap Sizes:* Stage 1: 8  $\mu\text{m}$   
Stage 2: 12  $\mu\text{m}$   
Stage 3: 18  $\mu\text{m}$   
Stage 4:  
Stage 5:

*Flow Angle:* 1/10

*Arrays/Chip:* 1

*Other:* central collection channel

Figure 49A shows the mask employed to fabricate the device. Figures  
10 49B-49D are enlargements of the portions of the mask that define the inlet,  
array, and outlet. Figures 50A-50G show SEMs of the actual device.

**Example 7.**

This device includes three stages, where each stage is a duplex having a  
15 bypass channel. "Fins" were designed to flank the bypass channel to keep fluid  
from the bypass channel from re-entering the array. The chip also included on-  
chip flow resistors, i.e., the inlets and outlets possessed greater fluidic  
resistance than the array. The height of the device was 117  $\mu\text{m}$ .

*Array Design:* 3 stage symmetric array

*Gap Sizes:* Stage 1: 8  $\mu\text{m}$   
Stage 2: 12  $\mu\text{m}$   
Stage 3: 18  $\mu\text{m}$   
Stage 4:  
Stage 5:

*Flow Angle:* 1/10

*Arrays/Chip:* 10

*Other:* large fin central collection channel  
on-chip flow resistors

Figure 51A shows the mask employed to fabricate the device. Figures 51B-51D are enlargements of the portions of the mask that define the inlet, array, and outlet. Figures 52A-52F show SEMs of the actual device.

#### **Example 8.**

This device includes three stages, where each stage is a duplex having a bypass channel. "Fins" were designed to flank the bypass channel to keep fluid from the bypass channel from re-entering the array. The edge of the fin closest to the array was designed to mimic the shape of the array. The chip also included on-chip flow resistors, i.e., the inlets and outlets possessed greater fluidic resistance than the array. The height of the device was 138  $\mu\text{m}$ .

<i>Array Design:</i>	3 stage symmetric array
<i>Gap Sizes:</i>	Stage 1: 8 $\mu\text{m}$ Stage 2: 12 $\mu\text{m}$ Stage 3: 18 $\mu\text{m}$ Stage 4: Stage 5:
<i>Flow Angle:</i>	1/10
<i>Arrays/Chip:</i>	10
<i>Other:</i>	alternate large fin central collection channel on-chip flow resistors

Figure 45A shows the mask employed to fabricate the device. Figures 45B-45D are enlargements of the portions of the mask that define the inlet, array, and outlet. Figures 532A-532F show SEMs of the actual device.

5

#### **Example 9.**

This device includes three stages, where each stage is a duplex having a bypass channel. "Fins" were optimized using Femlab to flank the bypass channel to keep fluid from the bypass channel from re-entering the array. The edge of the fin closest to the array was designed to mimic the shape of the array. The chip also included on-chip flow resistors, i.e., the inlets and outlets possessed greater fluidic resistance than the array. The height of the device was 139 or 142  $\mu\text{m}$ .

10

*Array Design:* 3 stage symmetric array

*Gap Sizes:* Stage 1: 8  $\mu\text{m}$   
Stage 2: 12  $\mu\text{m}$   
Stage 3: 18  $\mu\text{m}$   
Stage 4:  
Stage 5:

*Flow Angle:* 1/10

*Arrays/Chip:* 10

*Other:* Femlab optimized central collection channel (Femlab I)  
on-chip flow resistors

15

Figure 54A shows the mask employed to fabricate the device. Figures 54B-54D are enlargements of the portions of the mask that define the inlet, array, and outlet. Figures 55A-55S show SEMs of the actual device.

5           **Example 10.**

This device includes a single stage, duplex device having a bypass channel disposed to receive output from the ends of both arrays. The obstacles in this device are elliptical. The array boundary was modeled in Femlab. The chip also included on-chip flow resistors, i.e., the inlets and outlets possessed  
10 greater fluidic resistance than the array. The height of the device was 152  $\mu\text{m}$ .

*Array Design:*   single stage symmetric array

*Gap Sizes:*   Stage 1: 24  $\mu\text{m}$   
                  Stage 2:  
                  Stage 3:  
                  Stage 4:  
                  Stage 5:

*Flow Angle:*   1/60

*Arrays/Chip:*   14

*Other:*   central barrier  
            ellipsoid posts  
            on-chip resistors  
            Femlab modeled array boundary

Figure 44A shows the mask employed to fabricate the device. Figures 44B-44D are enlargements of the portions of the mask that define the inlet, array, and outlet. Figures 56A-56C show SEMs of the actual device.  
15

**Example 11.**

Though the following examples focus on extraction of a purified population of nuclei of circulating fetal cells from whole maternal blood, the methods described are generic for isolation of cellular components from other  
20 cells.

### Isolation of Fetal Nuclei

Figure 57 shows a flowchart for a method of isolating fetal nuclei from a maternal blood sample. The method results in the preferential lysis of red blood cells (Figure 58).

5           Several embodiments of a method that isolates from whole blood a purified population of nuclei from circulating cells of interest for genomic analysis are described below:

a) The method includes microfluidic processing, as described herein, of whole blood to 1) generate an enriched sample of nucleated cells by depletion  
10 of 1 to 3 log of the number of enucleated red blood cells and platelets, 2) release fetal nuclei by microfluidic processing of the enriched nucleated sample to lyse residual enucleated red cells, enucleated reticulocytes, and nucleated erythrocytes, preferentially over nucleated maternal white blood cells, 3)  
15 separate nuclei from maternal nucleated white blood cells by microfluidic processing through a size based device, and 4) analyze fetal genome using commercially available gene analysis tools.

b) The method can be designed to allow Steps 1 and 2 of Embodiment 1 in one pass through a microfluidic device, followed by use of a downstream device, or component of a larger device, for Step 3 (see Figures 59 & 60).  
20 Figure 59 shows a schematic diagram of a microfluidic device for producing concomitant enrichment and lysis. The device employs two regions of obstacles that deflect larger cells from the edges of the device, where the sample is introduced, into a central channel containing a lysis solution (e.g., a duplex device as described herein). For maternal blood, the regions of  
25 obstacles are disposed such that maternal enucleated red blood cells and platelets remain at the edges of the device, while fetal nucleated red blood cells and other nucleated cells are deflected into a central channel. Once deflected into the central channel, the fetal red blood cells (cells of interest) are lysed. Figure 60 shows a schematic diagram for a microfluidic device for separating  
30 nuclei (cellular component of interest) from unlysed cells. The device is similar to that of Figure 59, except the obstacles are disposed such that nuclei

remain at the edges of the device, while larger particles are deflected to the central channel.

c) A combination method of microfluidic based generation of fetal nuclei in maternal blood sample, followed by bulk processing techniques, such as density gradient centrifugation to separate the fetal nuclei from maternal cells (see Figure 61).

d) Methods and Proof of Principle

*Selective Lysis and Partitioning of Nucleated Erythrocytes.*

Contaminating red blood cells in donor blood samples spiked with full term cord blood were lysed using two methods, hypotonic and ammonium chloride lysis. Since enucleated red cells undergo lysis in hypotonic solution faster than nucleated cells, controlling the exposure time of the mixed cell population in the hypotonic solution will result in a differential lysis of cell populations based on this time. In this method, the cells are sedimented to form a pellet, and the plasma above the pellet is aspirated. Deionized water is then added, and the pellet is mixed with the water. Fifteen seconds of exposure is sufficient to lyse >95% of the enucleated red blood cells with minimal nucleated red blood cell lysis, 15 to 30 seconds of exposure is sufficient to lyse > 70% of the nucleated red blood cells but < 15% of other nucleated cells, and > 30 seconds will increase the percentage of lysis of other nucleated cells. After the desired exposure time, a 10× HBSS (hypertonic balanced salt) solution is added to return the solution back to isotonic conditions. Exposure to ammonium chloride lysing solutions at standard concentrations (e.g., 0.15 M isotonic solution) will lyse the bulk of red blood cells with minimal effects on nucleated cells. When the osmolality of the lysing solution is decreased to create a hypotonic ammonium chloride solution, the bulk of nucleated red blood cells are lysed along with the mature red blood cells.

Density centrifugation methods were used to obtain an enriched population of lymphocytes. An aliquot of these lymphocytes were exposed to a hypotonic ammonium chloride solution for sufficient time to lyse > 95% of the cells. These nuclei were then labeled with Hoechst 33342 (bisbenzimidazole H

33342), a specific stain for AT rich regions of double stranded DNA, and added back to the original lymphocyte population to create a 90:10 (cell: nuclei) mixture. This mixture was fed into a device that separated cells from nuclei based on size, as depicted in Figure 60, and the waste and product  
5 fractions were collected and the cell: nuclei ratio contained in each fraction were measured.

*Density Gradient Centrifugation of Lysed Product.* The lysed nuclei of mixed cell suspensions that have been processed through a differential lysis procedure can be enriched by adding a sucrose cushion solution to the lysate.  
10 This mixture is then layered on a pure sucrose cushion solution and then centrifuged to form an enriched nuclei pellet. The unlysed cells and debris are aspirated from the supernatant; the nuclei pellet is re-suspended in a buffer solution and then cytopun onto glass slides.

*Acid Alcohol Total Cell lysis and Nuclear RNA FISH for Targeted Cell*  
15 *Identification.* Product obtained from a device that separated cells based on size, as depicted in Figure 60, was exposed to an acid alcohol solution (methanol:acetic acid 3:1 v/v) for 30 minutes on ice resulting in the lysis of >99% of enucleated cells and >99.0% lysis of nucleated cells. A hypotonic treatment by exposing the cells to salt solution (0.6% NaCl) for 30 minutes to  
20 swell the nuclei before acid alcohol lysis can also be included. The released nuclei can be quantitatively deposited on to a glass slide by cytopspin and FISHed (Figure 66a and 66b). The cells of interest, such as fetal nucleated erythrocytes, can be identified using RNA-FISH with probes for positive selection, such as zeta-, epsilon, gamma-globins, and negative selection such as  
25 beta-globin or analyzing the length of telomeres. Other methods for distinguishing between fetal and non-fetal cells are known in the art, e.g., U.S. Patent No. 5,766,843.

#### **Example 12.**

30 Figure 62 shows a device that is optimized for separation of particles in blood. It is a one-stage device with a fixed gap width of 22µm, with 48

multiplexed arrays for parallel sample processing. The parameters of the device are as follows:

Array Design:	L5
Gap Sizes:	Stage 1: 22 $\mu$ m
Flow Angle:	1/50
Arrays/Chip:	48
Nominal Depth	150 $\mu$ m
Device Footprint	32 mm x 64 mm
Design Features	<ul style="list-style-type: none"> <li>• Multiplexed single arrays</li> <li>• Optimized bypass channels</li> <li>• Flow stabilization</li> <li>• Flow-feeding and Flow-extracting boundaries</li> </ul>

- 5 Blood was obtained from pregnant volunteer donors and diluted 1:1 with Dulbecco's phosphate buffered saline (without calcium and magnesium)(iDPBS). Blood and Running Buffer (iDPBS with 1% BSA and 2mM EDTA) were delivered using an active pressure of 0.8 PSI to the device engaged with a manifold as described in Example 13. Blood was separated
- 10 into two components nucleated cells in Running Buffer and enucleated cells and plasma proteins in Running Buffer. Both components were analyzed using a standard impedance counter. The component containing nucleated cells was additionally characterized using a propidium iodide staining solution in conjunction with a standard Nageotte counting chamber to determine total
- 15 nucleated cell loss. Data collected were used to determine blood process volume (mL), blood process rate (mL/hr), RBC/platelet removal, and nucleated cell retention. The following table provides results of cell enrichments employing this device:

Volume Processed (mL)	26.5	8	15.4	17	19
Throughput (mL/h)	10.6	10.0	11.8	9.8	9.8
WBC in the	0.013%	0.012%	0.005%	0.014%	0.030%

waste /input WBC (Nageotte)					
RBC Removal	99.993%	99.992%	99.997%	99.995%	99.999%
Platelet Removal	>99.6%	>99.7%	>99.7%	>99.7%	>99.7%

### Example 13.

An exemplary manifold into which a microfluidic device of the invention is inserted is shown in Figure 63. The manifold has two halves  
 5 between which a microfluidic device of the invention is disposed. One half of the manifold includes separate inlets for blood and buffer, each of which is connected to a corresponding fluid reservoir. The channels in the device are oriented so that they connect to the reservoirs via through holes in the device. Typically, the device is oriented vertically, and the processed blood is collected  
 10 as it drips out of the product outlet. A region around the product outlet of the microfluidic device may also be marked with a hydrophobic substance, e.g., from a permanent marker, to limit the size of drops formed. The device also includes two hydrophobic vent filters, e.g., 0.2  $\mu$ m PTFE filters. These filters allow air trapped in the device to be displaced by aqueous solutions, but do not  
 15 let the liquid pass at low pressures, e.g., < 5 psi.

To prime the device, buffer, e.g., Dulbecco's PBS with 1% bovine serum albumin (w/v) and 2 mM EDTA, is degassed for 5-10 min under reduced pressure and while being stirred. The buffer is then pumped into the device via the buffer inlet in the manifold at a pressure of < 5 psi. The buffer then fills the  
 20 buffer chamber by displacing air through the hydrophobic vent filter and then fills the channels in the microfluidic device and the blood chamber. A hydrophobic vent filter connected to the blood chamber allows for the displacement of air in the chamber. Once the blood chamber is filled, buffer is pumped into the blood inlet. In certain embodiments, after 1 minute of priming  
 25 at 1 psi, the blood inlet is clamped, and the pressure is increased to 3 psi for 3 minutes.

**Example 14.**

A fetal nRBC population enriched by any of the devices described herein is subjected to hypotonic shock by adding a large volume of low ionic strength buffer, e.g., deionized water to lyse enucleated RBCs and nRBCs  
5 selectively and release their nuclei. The hypotonic shock is then terminated by adding an equal volume of a high ionic strength buffer. The released nuclei, which may be subsequently harvested through gradient centrifugation such as passage through a solution of iodixanol in water,  $\rho = 1.32 \text{ g/mL}$ , are analyzed.

Figure 64 illustrates the selective lysis of fetal nRBCs vs. maternal  
10 nRBCs as a function of the duration of exposure to lysing conditions. This selective lysis procedure also can be used to lyse selectively fetal nRBCs in a population of cells composed of fetal nRBC, maternal nRBC, enucleated fetal and maternal RBCs, and fetal and maternal white blood cells. Using distilled water to induce hypotonic shock for a given time period and then adding an  
15 equal volume of  $10\times$  salt solution, such as PBS, to halt it, fetal nRBCs and maternal nRBCs were lysed over time during which the number of lysed (non-viable) fetal nRBCs increased by a factor of 10, whereas the number of lysed maternal nRBCs increased by a smaller multiple. At any given time point, the lysed cells were stained with propidium iodide and were concentrated through  
20 gradient centrifugation to determine the ratio of lysed fetal nRBCs vs. maternal nRBCs. An optimized time duration can be determined and applied to enrich selectively for fetal nRBCs nuclei.

**Example 15.**

25 To lyse enucleated RBCs and maternal nucleated RBCs selectively, a sample enriched in fetal nRBCs is treated with a RBC lysis buffer, such as  $0.155 \text{ M NH}_4\text{Cl}$ ,  $0.01 \text{ M KHCO}_3$ ,  $2 \text{ mM EDTA}$ ,  $1\% \text{ BSA}$  with a carbonic anhydrase inhibitor, such as acetazolamide (e.g., at  $0.1\text{-}100 \text{ mM}$ ), to induce lysis, followed by termination of the lysis process using a large volume of  
30 balanced salt buffer, such as  $10\times$  volume of  $1\times\text{PBS}$ , or balanced salt buffer, such as  $1\times\text{PBS}$ , with an ion exchange channel inhibitor such as 4,4'-

diisothiocyanostilbene-2,2'-disulphonic acid (DIDS). The surviving fetal cells may then be subjected to additional rounds of selection and analysis.

K562 cells, to simulate white blood cells, were labeled with Hoechst and calcein AM at room temperature for 30 minutes (Figure 65). These labeled  
5 K562 cells were added to blood specimens, followed by the addition of buffer (0.155 M NH<sub>4</sub>Cl, 0.01 M KHCO<sub>3</sub>, 2 mM EDTA, 1% BSA, and 10 mM acetazolamide) (the ratio of buffer volume to spiked blood volume is 3:2). The spiked blood specimens were incubated at room temperature for 4 hours with periodic gentle agitation. The fraction of viable cells in each spiked specimen  
10 were determined by measuring the green fluorescence at 610 nm at multiple time-points. Cell lysis is observed only after three minutes of treatment (in the absence of DIDS).

#### Example 16.

15 A sample enriched in fetal nRBC, e.g., by any of the devices or methods discussed herein, may be lysed and analyzed for genetic content. Possible methods of cell lysis and isolation of the desired cells or cell components include:

- a) A sample enriched in fetal nRBC may be subjected to *total cell lysis*  
20 to remove cytoplasm and isolate the nuclei. Nuclei may be immobilized through treatment with fixing solution, such as Carnoy's fix, and adhesion to glass slides. The fetal nuclei may be identified by the presence of endogenous fetal targets through immunostaining for nuclear proteins and transcription factors or  
25 through differential hybridization, RNA FISH of fetal pre-mRNAs (Gribnau et al. *Mol Cell* 2000. 377-86; Osborne et al. *Nat Gene*. 2004. 1065-71; Wang et al. *Proc. Natl. Acad. Sci.* 1991. 7391-7395; Alfonso-Pizarro et al. *Nucleic Acids Research*. 1984. 8363-8380.) These endogenous fetal targets may include globins such as zeta-,  
30 epsilon-, gamma-, delta-, beta-, alpha- and non-globin targets such as I-branching enzyme (Yu et al., *Blood*. 2003 101:2081), N-

acetylglucosamine transferase, or IgT. The oligo nucleotide probes employed by RNA FISH may be either for intron-exon boundaries or other regions, which uniquely identify the desired target or by analyzing the length of telomeres.

- 5           b) A sample enriched in fetal nRBC may be lysed selectively using treatments with buffers and ion exchange inhibitors described in example 15 to isolate fetal cells. The surviving fetal cells may be further subjected to selection by the presence or absence of intracellular markers such as globins and I-branching beta 1, 6- N-  
10           acetylglucosaminyltransferase or surface markers such as antigen I. In another embodiment, the enriched fetal nRBCs can be subjected to selective lysis to remove both the enucleated RBCs and maternal nRBCs as described in Example 15, followed by a complement mediated cell lysis using an antibody against CD45, a surface antigen  
15           present in all nucleated white blood cells. The resulting intact fetal nRBCs should be free of any other contaminating cells..
- c) A sample enriched in fetal nRBC may be lysed through hypotonic shock as described in Example 14 to isolate fetal nuclei. Nuclei may be immobilized through treatment with fixing solution, such as  
20           Carnoy's fix, and adhesion to glass slides.

          Once isolated, the desired cells or cell components (such as nuclei) may be analyzed for genetic content. FISH may be used to identify defects in chromosomes 13 and 18 or other chromosomal abnormalities such as trisomy 21 or XXY. Chromosomal aneuploidies may also be detected using methods  
25           such as comparative genome hybridization. Furthermore, the identified fetal cells may be examined using micro-dissection. Upon extraction, the fetal cells' nucleic acids may be subjected to one or more rounds of PCR or whole genome amplification followed by comparative genome hybridization, or short tandem repeats (STR) analysis, genetic mutation analysis such as single nucleotide  
30           point mutations (SNP), deletions, or translocations.

**Example 17.**

The product obtained from a device as depicted in Figure 60 including 3 ml of erythrocytes in 1xPBS is treated with 50 mM sodium nitrite/0.1 mM acetazolamide for 10 minutes. The cells are then contacted with a lysis buffer of 0.155 M  $\text{NH}_4\text{Cl}$ , 0.01 M  $\text{KHCO}_3$ , 2 mM EDTA, 1% BSA and 0.1 mM acetazolamide, and the lysis reaction is stopped by directly dripping into a quenching solution containing BAND 3 ion exchanger channel inhibitors such as 4,4'-diisothiocyanostilbene-2,2'-disulphonic acid (DIDS). The enucleated RBCs and nucleated RBCs are counted after Wright-Giemsa staining, and FISH is used to count the fetal nRBCs. Values are then compared to an unlysed control. One such experimental result is shown below:

	Before	After	Cell
Lysis	Lysis		Recovery %
eRBCs	$2.6 \times 10^6$	$0.03 \times 10^6$	~1%
nRBCs	42	26	62%
fnRBCs	6	4	68%

**Example 18.**

*Chaotropic Salt or Detergent Mediated Total Lysis and Oligo-Nucleotide Mediated Enrichment of Apoptotic DNA from Fetal Nucleated RBCs.* The product obtained from a device as depicted in Figure 60 is lysed in a chaotropic salt solution, such as buffered guanidinium hydrochloride solution (at least 4.0 M), guanidinium thiocyanate (at least 4.0 M) or a buffered detergent solution such as tris buffered solution with SDS. The cell lysate is then incubated at 55°C for 20 minutes with 10  $\mu\text{l}$  of 50mg/ml protease K to remove proteins and followed by a 5 minutes at 95°C to inactive protease. The fetal nRBCs undergo apoptosis when entering maternal blood circulation, and this apoptotic process leads to DNA fragmentation of fetal nRBC DNA. By taking advantage of reduced size of fetal nRBCs DNA and higher efficiency of isolating smaller DNA fragments over intact genomic DNA using oligonucleotide mediated enrichment, the apoptotic fetal nRBCs DNA can be

selectively enriched through hybridization to oligonucleotides in solution, attached to beads, or bound to an array or other surface in order to identify the unique molecular markers such as short tandem repeats (STR). After hybridization, the unwanted nucleic acids or other contaminants may be washed away with a high salt buffered solution, such as 150 mM sodium chloride in 10 mM Tris HCL pH 7.5, and the captured targets then released into a buffered solution, such as 10 mM Tris pH 7.8, or distilled water. The apoptotic DNA thus enriched is then analyzed using the methods for analysis of genetic content, e.g., as described in Example 16.

### Example 19

Figure 67 shows a flowchart detailing variations on lysis procedures that may be performed on maternal blood samples. Although illustrated as beginning with Enriched Product, e.g., produced using the devices and methods described herein, the processes may be performed on any maternal blood sample. The chart illustrates that lysis may be employed to lyse (i) wanted cells (e.g., fetal cells) selectively, (ii) wanted cells and their nuclei selectively, (iii) all cells, (iv) all cells and their nuclei, (v) unwanted cells (e.g., maternal RBCs, WBCs, platelets, or a combination thereof), (vi) unwanted cells and their nuclei, and (vii) lysis of all cells and selective lysis of nuclei of unwanted cells. The chart also shows exemplary methods for isolating released nuclei (devices and methods of the invention may also be used for this purpose) and methods for assaying the results.

### Example 20

This is an example of titrating whole cell lysis within a microfluidic environment. A blood sample enriched using size based separation as described herein was divided into 4 equal volumes. Three of the volumes were processed through a microfluidic device capable of transporting the cells into a first pre-defined medium for a defined path length within the device and then into a second pre-defined medium for collection. The volumetric cell

suspension flow rate was varied to allow controlled incubation times with the first pre-defined medium along the defined path length before contacting the second pre-defined medium. In this example DI water was used as the first pre-defined medium and 2× PBS was used as the second predefined medium.

- 5 Flow rates were adjusted to allow incubation times of 10, 20, or 30 seconds in DI water before the cells were mixed with 2× PBS to create an isotonic solution. Total cell numbers of the 3 processed volumes and the remaining unprocessed volume were calculated using a Hemacytometer

Sample	Starting Cell Count	Final Cell Count	% Remaining
1 unprocessed	$6.6 \times 10^6$	$6.6 \times 10^6$	100%
2 10 second exposure	$6.6 \times 10^6$	$7.2 \times 10^5$	10.9%
3 20 second exposure	$6.6 \times 10^6$	$4.6 \times 10^5$	6.9%
4 30 second exposure	$6.6 \times 10^6$	$3.4 \times 10^5$	5.2%

### Other Embodiments

All publications, patents, and patent applications mentioned in the above specification are hereby incorporated by reference. Various modifications and variations of the described method and system of the invention will be apparent to those skilled in the art without departing from the scope and spirit of the invention. Although the invention has been described in connection with specific embodiments, it should be understood that the invention as claimed should not be unduly limited to such specific embodiments. Indeed, various modifications of the described modes for carrying out the invention that are obvious to those skilled in the art are intended to be within the scope of the invention.

20

Other embodiments are in the claims.

What is claimed is:

## CLAIMS

1. A duplex device comprising a channel comprising a first section comprising first and second outer regions, each comprising a structure that deterministically directs particles having a hydrodynamic size above a critical size in a first direction and particles having a hydrodynamic size below said critical size in a second direction in said section, wherein said first and second outer regions are aligned in parallel in said channel.
2. The device of claim 1, wherein each structure comprises an array of obstacles that form a network of gaps, wherein a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network, wherein particles having a hydrodynamic size above said critical size in said first outer region are directed either toward said second outer region or away from said second outer region.
3. The device of claim 2, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.
4. The device of claim 1, further comprising a bypass channel disposed between said first and second outer regions in said first section, wherein each outer region independently directs said particles having a hydrodynamic size above said critical size toward or away from said bypass channel.
5. The device of claim 4, wherein the edges of the arrays disposed adjacent the central region comprise a flow-extracting boundary, wherein fluid

is extracted from the central region so that the flux of fluid in said central region is substantially constant.

6. The device of claim 2, further comprising a second section comprising three regions: first and second outer regions, each comprising an array of obstacles that form a network of gaps, wherein a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network, wherein particles having a hydrodynamic size above said critical size in, said first outer region are directed either toward said second outer region or away from said second outer region, and a third region comprising a first bypass channel disposed on the side of the first outer region in said second section to which the particles having a hydrodynamic size above said critical size are directed.

7. The device of claim 6, further comprising a second bypass channel disposed on the side of the second outer region in said second section to which the particles having a hydrodynamic size above said critical size are directed, wherein the first outer region directs particles having a hydrodynamic size above a critical size away from the second outer region, and the second outer region directs particles having a hydrodynamic size above a critical size away from the first outer region.

8. The device of claim 6, wherein the first bypass channel is disposed between said first and second outer regions in the second section and the first and second regions direct particles having a hydrodynamic size above a critical size toward said first bypass channel.

9. The device of claim 4, wherein the direction of said particles in said first and second outer region is toward said first bypass channel.

10. The device of claim 4, wherein the structure is capable of deflecting nucleated blood cells into the bypass channel and retaining enucleated blood cells in the first or second outer region.

11. A multi-stage device comprising:

(i) first and second sections aligned in series, wherein each section comprises a structure having first and second edges, wherein said structure deterministically directs particles having a hydrodynamic size above a critical size in a first direction and particles having a hydrodynamic size below said critical size in a second direction in said section; and

(ii) a first bypass channel disposed to receive fluidic output from the first or second edge of said first section, wherein said fluidic output does not pass through said second section.

12. The device of claim 11, wherein each structure comprises a channel comprising an array of obstacles that form a network of gaps, wherein the array has first and second edges, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network toward the first edge and particles having a hydrodynamic size below said critical size are not displaced laterally in said network toward the first edge.

13. The device of claim 12, wherein the array of obstacles in each section comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

14. The device of claim 11, wherein the first and second sections have different critical sizes.

15. The device of claim 11, wherein said first bypass channel is disposed to receive fluidic output from the first or second edge of said first and second sections.

16. The device of claim 15, wherein the width of said bypass channel adjacent each section is sized to have substantially the same fluidic resistance as the array in that section.

17. The device of claim 11, further comprising a second bypass channel, wherein said first bypass channel is disposed to receive fluidic output from the first or second edge of said first section, and said second bypass channel is disposed to receive fluidic output from the first or second edge of said second section.

18. The device of claim 12, further comprising a third section, wherein said third section comprises a channel comprising an array of obstacles that form a network of gaps, wherein the array has first and second edges parallel to the direction of fluidic flow, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network toward the first edge and particles having a hydrodynamic size below said critical size are not displaced laterally in said network toward the first edge.

19. The device of claim 18, wherein the first section has a critical size larger than said second section, and said second section has a critical size larger than said third section.

20. The device of claim 11, wherein said second section and said first bypass channel are sized to maintain substantially constant fluidic flux in said first and second sections.

21. A multiplex device comprising a plurality of channels, each channel comprising an inlet, an outlet, and a structure that deterministically directs particles having a hydrodynamic size above a critical size in a first direction and particles having a size below said critical size in a second direction in said channel.

22. The device of claim 21, wherein said structure comprises an array of obstacles that form a network of gaps, wherein a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network.

23. The device of claim 21, wherein the plurality of inlets are fluidically connected.

24. The device of claim 21, wherein the plurality of outlets are fluidically connected.

25. The device of claim 22, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

26. The device of claim 21, further comprising a bypass channel disposed between and fluidically connected to two of said structures.

27. The device of claim 21, wherein each structure is a multi-stage structure comprising first and second sections aligned in series, wherein each section comprises a structure having first and second edges, wherein said structure deterministically directs particles having a hydrodynamic size above a critical size in a first direction and particles having a hydrodynamic size below said critical size in a second direction in said section and a first bypass channel disposed to receive fluidic output from the first or second edge of said first section, wherein said fluidic output does not pass through said second section.

28. A device comprising a channel comprising an array of obstacles that form a network of gaps of a substantially constant width of 10-30 $\mu\text{m}$ , wherein fluid in blood passing through said gaps is divided unequally into a major flux and a minor flux so that cells having a hydrodynamic size above said critical size are displaced laterally in said network and cells having a hydrodynamic size below said critical size are not displaced laterally in said network.

29. The device of claim 28, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row, so that particles in the fluid are directed differentially based on their size.

30. The device of claim 28 wherein the width of said gaps is 18 - 24  $\mu\text{m}$ .

31. The device of claim 28 wherein said channel has one flow-feeding boundary and one flow-extracting boundary, and the width of said gaps is approximately 18 or 20  $\mu\text{m}$ .

32. A device comprising a channel comprising an array of obstacles that form a network of gaps of a substantially constant width, wherein fluid passing through said gaps is divided unequally into a major flux and a minor flux so that cells from a bodily fluid having a hydrodynamic size above said critical size are displaced laterally in said network and cells from a bodily fluid having a hydrodynamic size below said critical size are not displaced laterally in said network.

33. The device of claim 32, wherein said bodily fluid comprises sweat, tears, ear flow, sputum, lymph, bone marrow suspension, urine, saliva, semen, vaginal flow, cerebrospinal fluid, brain fluid, ascites, milk, secretions of the respiratory, intestinal or genitourinary tract, or amniotic fluid.

34. A device comprising a channel comprising a structure having first and second edges, wherein said structure deterministically deflects particles having a hydrodynamic size above a critical size toward the first edge, wherein the first edge or second edge comprises a flow-extracting or a flow-feeding boundary.

35. The device of claim 34, wherein said structure comprises an array of obstacles that form a network of gaps, wherein the array has first and second edges, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network.

36. The device of claim 35, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

37. A device comprising a channel comprising a separation region disposed to deflect deterministically a first blood component in a first direction and a second blood component in a second direction.

38. The device of claim 37, wherein said separation region comprises an array of obstacles that form a network of gaps, wherein a fluid passing through said gaps is divided unequally into a major flux and a minor so that particles having a hydrodynamic size above said critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network; wherein said first blood component has a hydrodynamic size above said critical size and said second blood component has a hydrodynamic size below said critical size.

39. The device of claim 38, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

40. The device of claim 37, wherein said first component comprises fetal nucleated cells, and said second component comprises maternal enucleated red blood cells.

41. The device of claim 40, wherein said fetal nucleated cell comprises a nucleated fetal red blood cell.

42. The device of claim 41, wherein said second component comprises maternal enucleated red blood cells.

43. A device comprising a channel comprising first and second sections aligned in series, wherein each section comprises a channel comprising a structure having first and second edges, wherein said structure

deterministically deflects particles having a hydrodynamic size above a critical size toward the first edge, wherein the interface between the first and second sections is not perpendicular to the direction of fluid flow.

44. The device of claim 43, wherein said structure comprises an array of obstacles that form a network of gaps, wherein the array has first and second edges, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above said critical size are displaced laterally in said network towards said first edge.

45. The device of claim 44, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

46. A device comprising a channel comprising an array of obstacles comprising first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above a critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network, wherein the bifurcation ratio is at most  $1/2$ .

47. The device of claim 46, wherein said ratio is at most  $1/60$ .

48. The device of claim 46, wherein the cross-section of said obstacles perpendicular to the average direction of flow is larger than cross-section of said obstacles parallel to the average direction of flow.

49. The device of claim 46, wherein red blood cells have a hydrodynamic size below said critical size, white blood cells have a

hydrodynamic size above said critical size, and said white blood cells do not block said array.

50. A device comprising a channel comprising first and second inlets and an array of obstacles that form a network of gaps, wherein a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above a critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network, wherein said first and second inlets have a greater fluidic resistance than said array.

51. The device of claim 50, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

52. A device comprising a channel comprising first and second outlets downstream of an array of obstacles that form a network of gaps, wherein a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above a critical size are displaced laterally in said network and particles having a hydrodynamic size below said critical size are not displaced laterally in said network, wherein said first and second outlets have a greater fluidic resistance than said array.

53. The device of claim 52, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

54. A device of any of claims 1, 11, 21, 28, 34, 37, 46, 50, and 52, wherein said device is coupled to an instrument for imaging of the output from said device.

55. A device comprising a channel comprising a structure having a first edge adjacent a first channel wall and a second edge adjacent a second channel wall, wherein said structure deterministically deflects particles having a hydrodynamic size above a critical size toward the first edge, wherein the first edge or second edge is spaced from the first or second channel wall by at least the critical size.

56. The device of claim 55, wherein said structure comprises an array of obstacles that form a network of gaps, wherein the array has first and second edges, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that particles having a hydrodynamic size above a critical size are displaced laterally in said network towards said first edge and particles having a hydrodynamic size below said critical size are not displaced laterally in said network towards said first edge.

57. The device of claim 56, wherein said array of obstacles comprises first and second rows, wherein the second row is displaced laterally relative to the first row so that fluid passing through a gap in the first row is divided unequally into two gaps in the second row.

58. A method for producing a sample enriched in a first biological particle, said method comprising the steps of:

- a. introducing a biological sample into the first or second outer region of a device of claim 1; and
- b. allowing said biological sample to flow through said device wherein any of said first biological particle present in said biological sample is

directed in said first or second direction, thereby producing said sample enriched in said first biological particle.

59. The method of claim 58, wherein said device is the device of claim 4, and said first and second outer regions direct particles having a hydrodynamic size above said critical size toward said bypass channel, and further comprising flowing a diluting solution in said bypass channel, wherein said first biological particle is directed into said bypass channel.

60. A method for producing a sample enriched in a first biological particle, said method comprising the steps of:

a. introducing a biological sample into the first section of a device of claim 11; and

b. allowing said biological sample to flow through said device wherein any of said first biological particle present in said biological sample is directed in said first or second direction of said first section, thereby producing said sample enriched in said first biological particle.

61. The method of claim 60, wherein said first biological particle is directed in said first direction of said first section and into said first bypass channel.

62. The method of claim 61, further comprising allowing the fluid not directed in said first direction of said first section to flow into said second section, wherein a second biological particle is directed in the first direction of said second section.

63. The method of claim 62, wherein said device is a device of claim 17, wherein said second biological particle is directed into said second bypass channel.

64. The method of claim 63, wherein a third biological particle is directed in the second direction of said second section.

65. The method of claim 64, wherein said first biological particle comprises white blood cells, said second biological particle comprises red blood cells, and said third biological particle comprises platelets.

66. A method for producing a sample enriched in a first biological particle, said method comprising the steps of:

- a. introducing a biological sample into the inlets of each channel of a device of claim 21; and
- b. allowing said biological sample to flow through said device, wherein any of said first biological particle present in said biological sample is directed in said first or second direction, thereby producing said sample enriched in said biological particle.

67. The method of any of claims 58, 60, and 66, further comprising collecting said sample enriched in said first biological particle.

68. The method of any of claims 58, 60, and 66, wherein the concentration of said first biological particle is increased in said enriched sample relative to said biological sample.

69. The method of any of claims 58, 60, and 66, wherein said biological sample comprises a cellular sample.

70. The method of claim 69, wherein said cellular sample comprises blood.

71. The method of any of claims 58, 60, and 66, wherein said biological sample comprises maternal blood and said first particle is a fetal cell.

72. The method of claim 71, wherein said fetal cell is a nucleated red blood cell.

73. The method of claim 71, further comprising analyzing said fetal cell for sex, aneuploidy, protein expression, coding or noncoding nucleic acid, or metabolic state.

74. A method for producing a sample enriched in a first biological particle, said method comprising the steps of:

- (a). introducing a biological sample into a device of claim 28; and
- (b) allowing said biological sample to flow through said network of gaps wherein any of said first biological particle present in said biological sample is directed in said first or second direction, thereby producing said sample enriched in said first biological particle.

75. The method of any of claims 58, 60, 66, and 74, wherein said first biological particle is a cancer cell, a pathogen, a parasite, a bacteria, a virus, a fungal cell, a host immune cell, a stem cell, a graft immune cell, a dendritic cell, a connective tissue cell, or a eukaryotic cell component.

76. The method of any of claims 58, 60, 66, and 74, wherein said biological sample is obtained from a first organism and first biological particle is from a second organism.

77. The method of any of claims 58, 60, 66, and 74, wherein said first and second organisms are different humans.

78. The method of any of claims 58, 60, 66, and 74, further comprising contacting, either before or during step (b), said first biological particle with a swelling reagent to increase the hydrodynamic radius of said first biological particle.

79. The method of any of claims 58, 60, 66, and 74, comprising contacting, either before or during step (b), said first biological particle with a shrinking reagent to decrease the hydrodynamic radius of said first biological particle.

80. The method of any of claims 58, 60, 66, and 74, wherein said biological sample comprises at most 90% liquid.

81. The method of any of claims 58, 60, 66, and 74, wherein said enriched sample comprises at least 75% of said first biological particle present in said biological sample.

82. The method of any of claims 58, 60, 66, and 74, wherein said first biological particle is enriched relative to the biological sample by a factor of at least 2.

83. The method of any of claims 58, 60, 66, and 74, wherein said first biological particle is not diluted by more than a factor of 10.

84. The method of any of claims 58, 60, 66, and 74, further comprising contacting said sample enriched in said first biological particle with a binding moiety that selectively binds said first biological particle or selectively binds a second biological particle.

85. The method of any of claims 58, 60, 66, and 74, further comprising analyzing said sample enriched in said first biological sample by RNA FISH to detect fetal nuclei.

86. The method of any of claims 58, 60, 66, and 74, wherein said first biological particle is a fetal nucleated cell.

87. The method of claim 86, wherein said fetal nucleated cell is a red blood cell, trophoblast, endothelial cell, or stem cell.

88. A method for altering a first biological particle, said method comprising the steps of:

(a) providing a device comprising a channel comprising a first inlet, a second inlet, a first outlet, a second outlet, and an array of obstacles that form a network of gaps, wherein the array has first and second edges parallel to the direction of fluidic flow, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that the average direction of the major flux is toward the first edge and the average direction of the minor flux is not toward the first edge;

(b) introducing a biological sample into said first inlet and introducing an altering liquid into said second inlet; and

(c) allowing said biological sample to flow through said network of gaps wherein any of said first biological particle present in said cellular sample is directed into said major flux and into said altering liquid, thereby altering said first biological particle.

89. The method of claim 88, wherein said altering liquid comprises a diluting or a labeling reagent.

90. The method of claim 88, wherein said labeling reagent comprises a megakaryocyte, a radioisotope, a fluorophore, a bead, or an antibody.

91. The method of claim 88, wherein said altering liquid comprises a stabilizing reagent.

92. The method of claim 91, wherein said stabilizing reagent comprises an apoptotic inhibitor, a fixative, an antioxidant, or a sugar.

93. The method of claim 92, wherein said sugar is sucrose or trehalose.

94. The method of claim 92, wherein said fixative is an aldehyde.

95. The method of claim 88, wherein said device is any device of claims 1, 11, 21, 28, 34, 37, 46, 50, and 52.

96. A method for producing an enriched, unactivated sample of a first cell or component thereof, said method comprising the steps of:

(a) providing a device comprising a channel comprising an array of obstacles that form a network of gaps, wherein the array has first and second edges parallel to the direction of fluidic flow, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that the average direction of the major flux is toward the first edge and the average direction of the minor flux is not toward the first edge;

(b) introducing a cellular sample into said array; and

(c) allowing said cellular sample to flow through said network of gaps wherein any of said first cell or component thereof present in said cellular sample is directed into said major flux, and wherein fewer than 10% of said first cell or component thereof undergo intracellular activation as a result of collisions between said first cell or component thereof with one of said obstacles, thereby producing said enriched, unactivated sample of said first cell or component thereof.

97. The method of claim 96, wherein said first cell is a platelet, a stem cell, a granulocyte, a monocyte, or an endothelial cell.

98. The method of claim 96, wherein said device is any device of claims 1, 11, 21, 28, 34, 37, 46, 50, and 52.

99. A method for producing a sample enriched in a first particle, said method comprising the steps of:

(a) providing a device comprising a channel comprising an array of obstacles that form a network of gaps, wherein the array has first and second edges parallel to the direction of fluidic flow, and a fluid passing through said gaps is divided unequally into a major flux and a minor flux so that the average direction of the major flux is toward the first edge and the average direction of the minor flux is not toward the first edge;

(b) introducing a sample comprising at least 0.1% particles by volume into said array; and

(c) allowing said sample to flow through said network of gaps wherein any of said first particle present in said sample is directed into said major flux, thereby producing said sample enriched in said first particle.

100. The method of claim 99, wherein said sample comprises blood.

101. The method of claim 99, wherein said device is any device of claims 1, 11, 21, 28, 34, 37, 46, 50, and 52.

102. A method for producing a sample enriched in a first blood component, said method comprising the steps of:

(a) providing a device of claim 37;

(b) introducing a sample comprising blood into said array; and

(c) allowing said sample to flow through said device such that said first blood component is separated from a second blood component deterministically, thereby producing said sample enriched in said first blood component.

103. The method of claim 102, wherein said device is the device of claim 38.

104. A method for collecting a cellular component from a cell of interest, comprising the steps of:

(a) treating a sample comprising the cell of interest to produce a sample enriched in the cell of interest;

(b) preferentially lysing cells of interest in the enriched sample over other cells comprising the cellular component or a counterpart thereof; and

(c) collecting the cellular component from lysed cells of interest.

105. The method of claim 103, further comprising analyzing the collected cellular component for identification, enumeration, or disease diagnosis.

106. The method of claim 103, wherein said cell of interest is a fetal red blood cell.

107. The method of claim 106, wherein said cellular component is a fetal red blood cell nucleus.

108. The method of claim 103, wherein said sample is a blood sample.

109. The method of claim 108, wherein said sample is a maternal blood sample.

110. The method of claim 103, wherein said cell of interest is a cancer cell, a pathogen, a parasite, a bacteria, a virus, a fungal cell, a host immune cell, a stem cell, a graft immune cell, a dendritic cell, or a connective tissue cell.

111. The method of claim 103, wherein said cellular component is an organelle, polymer or molecular complex, or an intracellular chemical species.

112. The method of claim 111, wherein said organelle is a nucleus, peri-nuclear compartment, nuclear membrane, mitochondrion, chloroplast, cell membrane, or intracellular parasite.

113. The method of claim 111, wherein said polymer or molecular complex is a lipid, polysaccharide, protein, nucleic acid, viral particle, or ribosome.

114. The method of claim 111, wherein said intracellular chemical species is a hormone, ion, cofactor, or drug.

115. The method of claim 103, wherein step (a) employs a device comprising a channel comprising a structure that deterministically deflects particles having a hydrodynamic size above a critical size in a direction not parallel to the average direction of flow in said section.

116. The method of claim 115, wherein steps (a) and (b) are concomitant.

117. A method for obtaining genetic information from circulating cells in a blood sample and said method comprising the steps of:

a. treating said blood sample to substantially eliminate enucleated red blood cells and platelets to produce an enriched nucleated cell sample;

- b. preferentially lysing nucleated cells of interest over other nucleated cells;
- c. collecting a nucleic acid containing cellular component of lysed cells of interest; and
- d. analyzing nucleic acid in the collected cellular component, thereby obtaining genetic information from the cell of interest.

118. The method of claim 117, wherein said cell of interest is a fetal red blood cell.

119. The method of claim 117, wherein said cell of interest is a cancer cell, a pathogen, a parasite, a bacteria, a virus, a fungal cell, a host immune cell, a stem cell, a graft immune cell, a dendritic cell, or a connective tissue cell.

120. The method of claim 117, wherein said cellular component is an organelle, polymer or molecular complex, or an intracellular chemical species.

121. The method of claim 120, wherein said organelle is a nucleus, peri-nuclear compartment, nuclear membrane, mitochondrion, chloroplast, cell membrane, or intracellular parasite.

122. The method of claim 120, wherein said polymer or molecular complex is a lipid, polysaccharide, protein, nucleic acid, viral particle, or ribosome.

123. The method of claim 120, wherein said intracellular chemical species is a hormone, ion, cofactor, or drug.

124. The method of claim 117, wherein said genetic information comprises disease status, gender, paternity, aneuploidy, or presence or absence of a mutation.

125. The method of claim 117, wherein step (a) employs a device comprising a channel comprising a structure that deterministically deflects particles having a hydrodynamic size above a critical size in a direction not parallel to the average direction of flow in said section.

126. The method of claim 125, wherein steps (a) and (b) are concomitant.

127. A manifold comprising:

(a) a first reservoir, a first inlet in fluid communication with said first reservoir, and a first hydrophobic vent in fluid communication with said first reservoir; and

(b) an outlet,

wherein said manifold is shaped and sized to engage a microfluidic device capable of enriching a first particle in a sample relative to a second component of said sample based on size, shape, deformability, or affinity, wherein said first reservoir and outlet are in fluid communication when said microfluidic device is engaged and are not in fluid communication when said microfluidic device is not engaged.

128. The manifold of claim 127, further comprising a second reservoir, a second inlet in fluid communication with said second reservoir, and optionally a second hydrophobic vent in fluid communication with said second reservoir wherein said first reservoir, second reservoir, and outlet are in fluid communication when said microfluidic device is engaged and are not in fluid communication when said microfluidic device is not engaged.

129. The manifold of claim 128, wherein said first or second hydrophobic vent comprises  $<1\ \mu\text{m}$  pores.

130. The manifold of claim 127, wherein said manifold comprises two halves, wherein said microfluidic device can be engaged by being disposed between said halves.

131. The manifold of claim 127, wherein said first reservoir fluidically communicates with a channel in said microfluidic device via through holes in said device.

132. The manifold of claim 128 wherein said first and second reservoirs fluidically communicate with a channel in said microfluidic device via through holes in said device.

133. The manifold of claim 127 or 128 wherein said manifold is shaped and sized to engage a plurality of said microfluidic devices.

134. The manifold of claim 128, wherein said microfluidic device comprises a channel having a structure that deterministically directs particles having a hydrodynamic size above a critical size in a first direction and particles having a hydrodynamic size below said critical size in a second direction.

135. The manifold of claim 134, wherein said microfluidic device is a device of any of claims 1 - 57.

136. The manifold of claim 127 or 128, further comprising said microfluidic device being engaged.

137. The manifold of claim 127 or 128, wherein said microfluidic device comprises a plurality of channels, each of which is capable of independently enriching a first particle in a sample relative to a second component of said sample based on size, shape, deformability, or affinity.

138. The manifold of claim 137, wherein said plurality of channels is at least 5, 10, 15, 20, 25, or 30.

139. The manifold of claim 137, wherein each channel is independently connected to said first and/or second reservoirs via through holes in said device.

140. The manifold of claim 127 - 139, wherein said first particle comprises a cancer cell, a pathogen, a parasite, a bacteria, a virus, a fungal cell, a host immune cell, a stem cell, a graft immune cell, a dendritic cell, a connective tissue cell, or a eukaryotic cell component.

141. The manifold of claim 127 - 139, wherein said first particle comprises a nucleated red blood cell.

142. The manifold of claim 141, wherein said first particles comprises a fetal nucleated red blood cell.

143. A method of enriching a first particle relative to a second component in a sample, said method comprising the steps of:

(a) introducing said sample via the first inlet into a manifold engaged with a microfluidic device of claim 136, wherein said sample at least partially fills said first reservoir; and

(b) allowing said sample to pass through said microfluidic device to enrich said first particles relative to said second component based on size, shape, deformability, or affinity.

144. The method of claim 143, wherein said manifold is a manifold of claim 128, and further comprising, prior to step (b), introducing a second liquid via the second inlet into the manifold, wherein said second liquid at least

partially fills said second reservoir, wherein during step (b), said second liquid interacts with said sample.

145. The method of claim 144, wherein said microfluidic device comprises a channel having a structure that deterministically directs particles having a hydrodynamic size above a critical size in a first direction and particles having a hydrodynamic size below said critical size in a second direction.

146. The method of claim 145, wherein said microfluidic device is a device of any of claims 1 - 57.

147. The method of claim 143, wherein said manifold is the manifold of claims 129 - 142.

148. A method of introducing a liquid into a manifold, said method comprising the steps of:

(a) providing a manifold of claim 127 further comprising the microfluidic device, wherein said manifold and device are not filled with liquid;

(b) introducing the liquid via the first inlet into the manifold, wherein said liquid at least partially fills the first reservoir and displaces gas present in the first reservoir through said first hydrophobic vent, wherein said introducing occurs at a pressure insufficient to force the liquid through said first vent; and

(c) allowing the liquid to enter the microfluidic device and pass through the outlet.

149. The method of claim 148, wherein said manifold is the manifold of claim 128, wherein before, during, or after step (c), the liquid flows from said first reservoir through said microfluidic device and into said

second reservoir, wherein said liquid displaces gas through said second hydrophobic vent.

150. The method of claim 148, wherein said manifold is the manifold of claims 129 - 142.

151. A method of enriching a sample in fetal cells relative to maternal cells, said method comprising:

(a) introducing a maternal blood sample into a microfluidic device capable of enriching fetal nucleated cells relative to maternal cells based on size, shape, deformability, or affinity to produce an enriched sample;

(b) lysing said fetal nucleated cells in said enriched sample to release fetal nuclei; and

(c) detecting said fetal nuclei.

152. The method of claim 151, wherein step b comprises lysing all cells in said enriched sample and collecting said fetal nuclei.

153. The method of claim 151, wherein step b comprises selectively lysing fetal nucleated cells relative to maternal cells.

154. The method of claim 151, wherein said microfluidic device comprises a channel having a structure that deterministically directs fetal nucleated cells in a first direction and at least some maternal cells in a second direction based on deterministic lateral displacement.

155. The method of claim 154, wherein said microfluidic device is a device of any of claims 1 - 57.

156. The method of claim 151, wherein step c comprises employing RNA FISH for positive or negative selection of said fetal nuclei.

157. A method of enriching a maternal blood sample in fetal cells, said method comprising the steps of:

- (a) providing said maternal blood sample;
- (b) contacting said sample with a buffer comprising ammonium and bicarbonate ions and a carbonic anhydrase inhibitor to induce selective lysis of maternal red blood cells relative to fetal red blood cells; and
- (c) introducing a band 3 anion translocator inhibitor to halt lysis.

158. The method of claim 157, wherein said sample in step a is enriched for said fetal cells via a microfluidic device capable of enriching said fetal cells relative to maternal cells based on size, shape, deformability, or affinity.

159. The method of claim 158, wherein said microfluidic device comprises a channel having a structure that deterministically directs fetal nucleated cells in a first direction and at least some maternal cells in a second direction based on deterministic lateral displacement.

160. The method of claim 159, wherein said microfluidic device is a device of any of claims 1 - 57.

161. The method of claim 157, wherein said carbonic anhydrase inhibitor comprises acetazolamide.

162. The method of claim 157, wherein said band 3 anion translocator inhibitor comprises DIDS.

163. A method of enriching a maternal blood sample in fetal cells, said method comprising the steps of:

- a. providing said maternal blood sample; and

- b. contacting said sample with one or more buffers capable of inducing selective lysis of maternal red blood cells and white blood cells relative to fetal red blood cells.

164. A method of analyzing fetal cells in a sample, said method comprising the steps of:

- a. providing a maternal blood sample;
- b. performing one of the following lysis procedures on said sample:
  - (i) selectively lysing fetal cells relative to a maternal cell while keeping fetal nuclei intact;
  - (ii) selectively lysing a maternal cell relative to a fetal cell while keeping maternal nuclei intact;
  - (iii) lysing all cells while keeping their nuclei intact;
  - (iv) lysing all cells and maternal nuclei while keeping fetal nuclei intact;
  - (v) selectively lysing maternal cells and their nuclei relative to fetal cells;
  - (vi) lysing all cells and their nuclei; and
  - (vii) selectively lysing fetal cells and their nuclei relative to maternal cells; and
- c. analyzing a fetal nucleus, fetal nucleic acid, fetal protein, or fetal metabolite released by step (b).

165. The method of claim 164, wherein said sample of step (a) is enriched for said fetal cells via a microfluidic device capable of enriching said fetal cells relative to maternal cells based on size, shape, deformability, or affinity.

166. The method of claim 165, wherein said microfluidic device comprises a channel having a structure that deterministically directs fetal

nucleated cells in a first direction and at least some maternal cells in a second direction based on deterministic lateral displacement.

167. The method of claim 165, wherein said microfluidic device is a device of any of claims 1 - 57.

168. The method of claim 164, wherein step (c) comprises analyzing said fetal nucleus, fetal nucleic acid, fetal protein, or fetal metabolite by RNA or DNA FISH, PCR, telomere length analysis, affinity-based assay, or DNA or RNA hybridization.
